Non-Confidential - Beta

G6.2.116 SCR, Secure Configuration Register

The SCR characteristics are:

Purpose

When EL3 is implemented and can use AArch32, defines the configuration of the current Security state. It specifies:

- The Security state, either Secure or Non-secure.
- What mode the PE branches to if an IRQ, FIQ, or External Abort occurs.
- Whether the CPSR.F or CPSR.A bits can be modified when SCR.NS==1.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1 (NS)	EL1 (S)	EL2 (NS)
-	-	Trap	-

If EL3 is implemented and is using AArch64, any read or write to SCR from Secure EL1 using AArch32 is trapped as an exception to EL3.

If EL3 is not implemented, accesses to the SCR are UNDEFINED.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

This register is only accessible in Secure state.

AArch32 System register SCR can be mapped to AArch64 System register SCR_EL3, but this is not architecturally mandated.

Some or all RW fields of this register have defined reset values. These apply whenever the register is accessible. This means they apply when the PE resets into EL3 using AArch32.

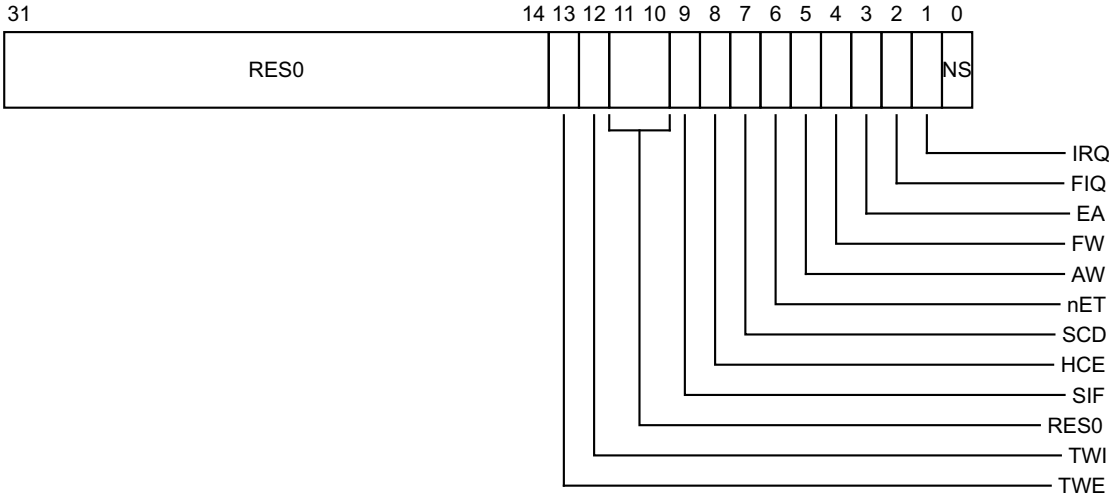
Attributes

SCR is a 32-bit register.

Field descriptions

The SCR bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



Bits [31:14]

Reserved, RES0.

TWE, bit [13]

Traps WFE instructions to Monitor mode.

`0` This control has no effect on the execution of WFE instructions.

`1` Any attempt to execute a WFE instruction in any mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state and the attempted execution does not generate an exception that is taken to EL1 or EL2.

Any exception that is taken to EL1 or to EL2 has priority over this trap.

The attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When this register has an architecturally-defined reset value, this field resets to `0`.

TWI, bit [12]

Traps WFI instructions to Monitor mode.

`0` This control has no effect on the execution of WFI instructions.

`1` Any attempt to execute a WFI instruction in any mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state and the attempted execution does not generate an exception that is taken to EL1 or EL2.

Any exception that is taken to EL1 or to EL2 has priority over this trap.

The attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When this register has an architecturally-defined reset value, this field resets to `0`.

Bits [11:10]

Reserved, RES0.

SIF, bit [9]

Secure instruction fetch. When the PE is in Secure state, this bit disables instruction fetch from Non-secure memory. The possible values for this bit are:

`0` Secure state instruction fetches from Non-secure memory are permitted.

`1` Secure state instruction fetches from Non-secure memory are not permitted.

This bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to `0`.

HCE, bit [8]

Hypervisor Call instruction enable. Enables EL2 and Non-secure EL1 execution of HVC instructions.

`0` HVC instructions are:

- UNDEFINED at Non-secure EL1. The Undefined Instruction exception is taken from PL1 to PL1.
- UNPREDICTABLE at EL2. Behavior is one of the following:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.

`1` HVC instructions are enabled at EL2 and Non-secure EL1.

Note

HVC instructions are always UNDEFINED at EL0 and in Secure state.

If EL2 is not implemented, this bit is RES0 and HVC is UNDEFINED.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, this field resets to `0`.

SCD, bit [7]

Secure Monitor Call disable. Disables SMC instructions.

`0` SMC instructions are enabled.

`1` In Non-secure state, SMC instructions are UNDEFINED. The Undefined Instruction exception is taken from the current Exception level to the current Exception level.

In Secure state, behavior is one of the following:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

Note

SMC instructions are always UNDEFINED at PL0.

When this register has an architecturally-defined reset value, this field resets to `0`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

nET, bit [6]

Not Early Termination. This bit disables early termination. The possible values of this bit are:

0 Early termination permitted. Execution time of data operations can depend on the data values.

1 Disable early termination. The number of cycles required for data operations is forced to be independent of the data values.

This IMPLEMENTATION DEFINED mechanism can disable data dependent timing optimizations from multiplies and data operations. It can provide system support against information leakage that might be exploited by timing correlation types of attack.

On implementations that do not support early termination or do not support disabling early termination, this bit is RES0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, this field resets to 0.

AW, bit [5]

When the value of SCR.EA is 1 and the value of HCR.AMO is 0, this bit controls whether CPSR.A masks an external abort taken from Non-secure state, and the possible values of this bit are:

0 External aborts taken from Non-secure state are not masked by CPSR.A, and are taken to EL3.

External aborts taken from Secure state are masked by CPSR.A.

1 External aborts taken from either Security state are masked by CPSR.A. When CPSR.A is 0, the abort is taken to EL3.

When SCR.EA is 0 or HCR.AMO is 1, this bit has no effect.

When this register has an architecturally-defined reset value, this field resets to 0.

FW, bit [4]

When the value of SCR.FIQ is 1 and the value of HCR.FMO is 0, this bit controls whether CPSR.F masks an FIQ interrupt taken from Non-secure state, and the possible values of this bit are:

0 An FIQ taken from Non-secure state is not masked by CPSR.F, and is taken to EL3.

An FIQ taken from Secure state is masked by CPSR.F.

1 An FIQ taken from either Security state is masked by CPSR.F. When CPSR.F is 0, the FIQ is taken to EL3.

When SCR.FIQ is 0 or HCR.FMO is 1, this bit has no effect.

When this register has an architecturally-defined reset value, this field resets to 0.

EA, bit [3]

External Abort handler. This bit controls which mode takes external aborts. The possible values of this bit are:

0 External aborts taken to Abort mode.

1 External aborts taken to Monitor mode.

When this register has an architecturally-defined reset value, this field resets to 0.

FIQ, bit [2]

FIQ handler. This bit controls which mode takes FIQ exceptions. The possible values of this bit are:

0 FIQs taken to FIQ mode.

1 FIQs taken to Monitor mode.

When this register has an architecturally-defined reset value, this field resets to 0.

IRQ, bit [1]

IRQ handler. This bit controls which mode takes IRQ exceptions. The possible values of this bit are:

0 IRQs taken to IRQ mode.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

1 IRQs taken to Monitor mode.

When this register has an architecturally-defined reset value, this field resets to 0.

NS, bit [0]

Non-secure bit. Except when the PE is in Monitor mode, this bit determines the Security state of the PE:

0 PE is in Secure state.

1 PE is in Non-secure state.

If the HCR.TGE bit is set, an attempt to change from a Secure PL1 mode to a Non-secure EL1 mode by changing the SCR.NS bit from 0 to 1 results in the SCR.NS bit remaining as 0.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the SCR:

To access the SCR:

```
MRC p15,0,<Rt>,c1,c1,0 ; Read SCR into Rt
MCR p15,0,<Rt>,c1,c1,0 ; Write Rt to SCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0001	0001	000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.2.117 SCTLR, System Control Register

The SCTLR characteristics are:

Purpose

Provides the top level control of the system, including its memory system.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

SCTLR(S) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	-	RW

SCTLR(NS) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	-

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

SCTLR is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

Some bits in the register are read-only. These bits relate to non-configurable features of an implementation, and are provided for compatibility with previous versions of the architecture.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.

If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.

If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register SCTLR is architecturally mapped to AArch64 System register SCTLR_EL1.

When EL3 is using AArch32, write access to SCTLR(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

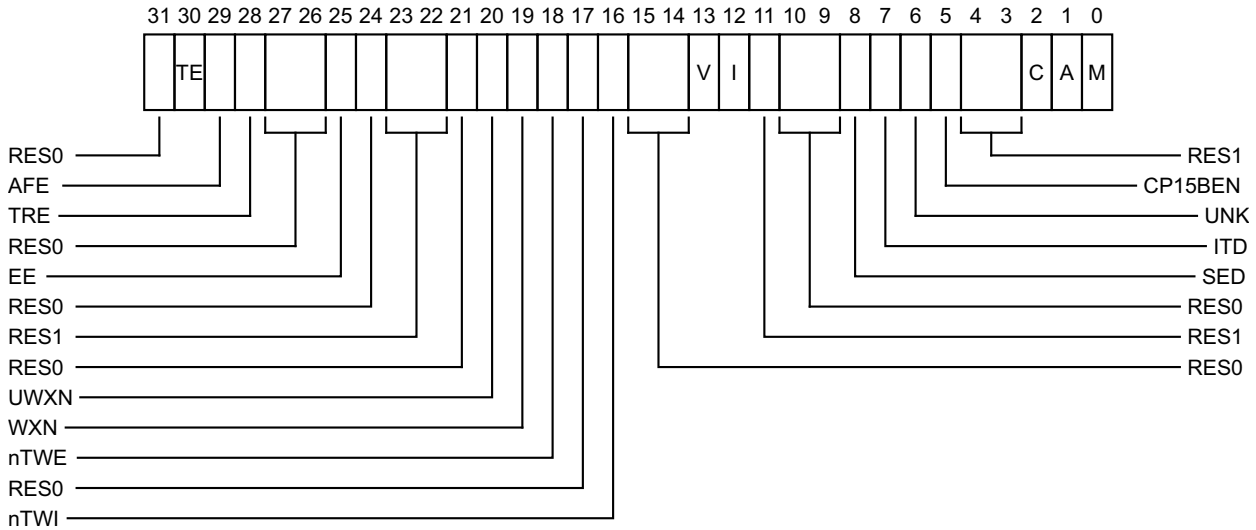
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. If the PE resets into EL3 using AArch32 they apply only to the Secure instance of the register. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

SCTLR is a 32-bit register.

Field descriptions

The SCTLR bit assignments are:



Bit [31]

Reserved, RES0.

TE, bit [30]

T32 Exception Enable. This bit controls whether exceptions to an Exception Level that is executing at PL1 are taken to A32 or T32 state:

0 Exceptions, including reset, taken to A32 state.

1 Exceptions, including reset, taken to T32 state.

When this register has an architecturally-defined reset value, this field resets to an IMPLEMENTATION DEFINED choice between:

- 0.
- A value determined by an input configuration signal.

AFE, bit [29]

Access Flag Enable. When using the Short-descriptor translation table format for the PL1&0 translation regime, this bit enables use of the AP[0] bit in the translation descriptors as the Access flag, and restricts access permissions in the translation descriptors to the simplified model. The possible values of this bit are:

0 In the translation table descriptors, AP[0] is an access permissions bit. The full range of access permissions is supported. No Access flag is implemented.

1 In the translation table descriptors, AP[0] is the Access flag. Only the simplified model for access permissions is supported.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

When using the Long-descriptor translation table format, the VMSA behaves as if this bit is set to 1, regardless of the value of this bit.

The AFE bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to `0`.

TRE, bit [28]

TEX remap enable. This bit enables remapping of the TEX[2:1] bits in the PL1&0 translation regime for use as two translation table bits that can be managed by the operating system. Enabling this remapping also changes the scheme used to describe the memory region attributes in the VMSA. The possible values of this bit are:

`0` TEX remap disabled. TEX[2:0] are used, with the C and B bits, to describe the memory region attributes.

`1` TEX remap enabled. TEX[2:1] are reassigned for use as bits managed by the operating system. The TEX[0], C, and B bits are used to describe the memory region attributes, with the MMU remap registers.

When the value of TTBCR.EAE is 1, this bit is RES1.

The TRE bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to `0`.

Bits [27:26]

Reserved, RES0.

EE, bit [25]

The value of the PSTATE.E bit on branch to an exception vector or coming out of reset, and the endianness of stage 1 translation table walks in the PL1&0 translation regime.

The possible values of this bit are:

`0` Little-endian. PSTATE.E is cleared to 0 on taking an exception or coming out of reset. Stage 1 translation table walks in the PL1&0 translation regime are little-endian.

`1` Big-endian. PSTATE.E is cleared to 0 on taking an exception or coming out of reset. Stage 1 translation table walks in the PL1&0 translation regime are big-endian.

If an implementation does not provide Big-endian support for data accesses at Exception Levels higher than EL0, this bit is RES0.

If an implementation does not provide Little-endian support for data accesses at Exception Levels higher than EL0, this bit is RES1.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, this field resets to an IMPLEMENTATION DEFINED choice between:

- `0`.
- A value determined by an input configuration signal.

Bit [24]

Reserved, RES0.

Bits [23:22]

Reserved, RES1.

Bit [21]

Reserved, RES0.

UWXN, bit [20]

Unprivileged write permission implies PL1 XN (Execute-never). This bit can force all memory regions that are writeable at PL0 to be treated as XN for accesses from software executing at PL1. The possible values of this bit are:

`0` This control has no effect on memory access permissions.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

1 Any region that is writeable at PL0 forced to XN for accesses from software executing at PL1.

The UWXN bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.

WXN, bit [19]

Write permission implies XN (Execute-never). For the PL1&0 translation regime, this bit can force all memory regions that are writeable to be treated as XN. The possible values of this bit are:

0 This control has no effect on memory access permissions.

1 Any region that is writeable in the PL1&0 translation regime is forced to XN for accesses from software executing at PL1 or PL0.

The WXN bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.

nTWE, bit [18]

Traps PL0 execution of WFE instructions to Undefined mode.

0 Any attempt to execute a WFE instruction at PL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.

1 This control has no effect on the PL0 execution of WFE instructions.

The attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When this register has an architecturally-defined reset value, this field resets to 1.

Bit [17]

Reserved, RES0.

nTWI, bit [16]

Traps PL0 execution of WFI instructions to Undefined mode.

0 Any attempt to execute a WFI instruction at PL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.

1 This control has no effect on the PL0 execution of WFI instructions.

The attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When this register has an architecturally-defined reset value, this field resets to 1.

Bits [15:14]

Reserved, RES0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

V, bit [13]

Vectors bit. This bit selects the base address of the exception vectors for exceptions taken to a PE mode other than Monitor mode or Hyp mode:

`0` Normal exception vectors. Base address is held in VBAR.

`1` High exception vectors (Hivecs), base address `0xFFFF0000`. This base address cannot be remapped.

When this register has an architecturally-defined reset value, this field resets to an IMPLEMENTATION DEFINED choice between:

- `0`.
- A value determined by an input configuration signal.

I, bit [12]

Instruction cache enable. This is a global enable bit for instruction caches:

`0` All instruction access to Normal memory from PL1 and PL0 are Non-cacheable for all levels of instruction and unified cache.

If the value of SCTLR.M is 0, instruction accesses from stage 1 of the PL1&0 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.

`1` All instruction access to Normal memory from PL1 and PL0 can be cached at all levels of instruction and unified cache.

If the value of SCTLR.M is 0, instruction accesses from stage 1 of the PL1&0 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

Instruction accesses to Normal memory from Non-secure EL1 and Non-secure EL0 are Cacheable regardless of the value of the SCTLR.I bit if either:

- EL2 is using AArch32 and the value of HCR.DC is 1.
- EL2 is using AArch64 and the value of HCR_EL2.DC is 1.

When this register has an architecturally-defined reset value, this field resets to `0`.

Bit [11]

Reserved, RES1.

Bits [10:9]

Reserved, RES0.

SED, bit [8]

SETEND instruction disable. Disables SETEND instructions at PL0 and PL1.

`0` SETEND instruction execution is enabled at PL0 and PL1.

`1` SETEND instructions are UNDEFINED at PL0 and PL1.

If the implementation does not support mixed-endian operation at any Exception level, this bit is RES1.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, this field resets to `0`.

ITD, bit [7]

IT Disable. Disables some uses of IT instructions at PL1 and PL0.

`0` All IT instruction functionality is enabled at PL1 and PL0.

`1` Any attempt at PL1 or PL0 to execute any of the following is UNDEFINED:

- All encodings of the IT instruction with hw1[3:0]!=1000.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- All encodings of the subsequent instruction with the following values for hw1:

  `11xxxxxxxxxxxxx`

  All 32-bit instructions, and the 16-bit instructions B, UDF, SVC, LDM, and STM.

  `1011xxxxxxxxxxx`

  All instructions in *Miscellaneous 16-bit instructions* on page F3-2356.

  `10100xxxxxxxxxx`

  ADD Rd, PC, #imm

  `01001xxxxxxxxxx`

  LDR Rd, [PC, #imm]

  `0100x1xxx1111xxx`

  ADD Rdn, PC; CMP Rn, PC; MOV Rd, PC; BX PC; BLX PC.

  `010001xx1xxxx111`

  ADD PC, Rm; CMP PC, Rm; MOV PC, Rm. This pattern also covers UNPREDICTABLE cases with BLX Rn.

  These instructions are always UNDEFINED, regardless of whether they would pass or fail the condition code check that applies to them as a result of being in an IT block.

  It is IMPLEMENTATION DEFINED whether the IT instruction is treated as:

  - A 16-bit instruction, that can only be followed by another 16-bit instruction.
  - The first half of a 32-bit instruction.

  This means that, for the situations that are UNDEFINED, either the second 16-bit instruction or the 32-bit instruction is UNDEFINED.

  An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

ITD is optional, but if it is implemented in the SCTLR then it must also be implemented in the SCTLR_EL1. If it is not implemented then this bit is RAZ/WI.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, this field resets to `0`.

UNK, bit [6]

Writes to this bit are IGNORED. Reads of this bit return an UNKNOWN value.

CP15BEN, bit [5]

CP15 memory barrier enable. Enables accesses to the CP15 DMB, DSB, and ISB barrier operations from PL1 and PL0:

`0` PL0 and PL1 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is UNDEFINED.

`1` PL0 and PL1 execution of the CP15DMB, CP15DSB, and CP15ISB instructions is enabled.

CP15BEN is optional, but if it is implemented in the SCTLR then it must also be implemented in the SCTLR_EL1. If it is not implemented then this bit is RAO/WI.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, this field resets to `1`.

Bits [4:3]

Reserved, RES1.

C, bit [2]

Cache enable, for data caching.

`0` All data access to Normal memory from PL1 and PL0, and all accesses to the PL1&0 stage 1 translation tables, are Non-cacheable for all levels of data and unified cache.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

1 All data access to Normal memory from PL1 and PL0, and all accesses to the PL1&0 stage 1 translation tables, can be cached at all levels of data and unified cache.

The PE ignores SCLTR.C for Non-secure state and data accesses to Normal memory from EL1 and EL0 are Cacheable if either:

- EL2 is using AArch32 and the value of HCR.DC is 1.
- EL2 is using AArch64 and the value of HCR_EL2.DC is 1.

When this register has an architecturally-defined reset value, this field resets to 0.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at PL1 and PL0:

0 Alignment fault checking disabled when executing at PL1 or PL0.

Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

1 Alignment fault checking enabled when executing at PL1 or PL0.

All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

When this register has an architecturally-defined reset value, this field resets to 0.

M, bit [0]

MMU enable for EL1 and EL0 stage 1 address translation. Possible values of this bit are:

0 EL1 and EL0 stage 1 address translation disabled.

See the SCTLR.I field for the behavior of instruction accesses to Normal memory.

1 EL1 and EL0 stage 1 address translation enabled.

In the Non-secure state the PE behaves as if the value of the SCTLR.M field is 0 for all purposes other than returning the value of a direct read of the field if either:

- EL2 is using AArch32 and the value of HCR.{DC, TGE} is not {0, 0}.
- EL2 is using AArch64 and the value of HCR_EL2.{DC, TGE} is not {0, 0}.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the SCTLR:

To access the SCTLR:

```
MRC p15,0,<Rt>,c1,c0,0 ; Read SCTLR into Rt
MCR p15,0,<Rt>,c1,c0,0 ; Write Rt to SCTLR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0001	0000	000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.2.118 SPSR, Saved Program Status Register

The SPSR characteristics are:

Purpose

Holds the saved process state for the current mode.

Usage constraints

The SPSR can be read using the MRS instruction and written using the MSR (immediate) or MSR (register) instructions. For more details on the instruction syntax, see *PSTATE and banked register access instructions* on page F1-2296.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

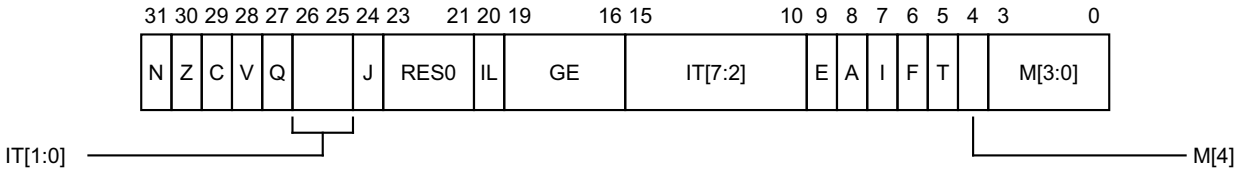
There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

SPSR is a 32-bit register.

Field descriptions

The SPSR bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to the current mode, and copied to CPSR.N on executing an exception return operation in the current mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to the current mode, and copied to CPSR.Z on executing an exception return operation in the current mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to the current mode, and copied to CPSR.C on executing an exception return operation in the current mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to the current mode, and copied to CPSR.V on executing an exception return operation in the current mode.

Q, bit [27]

Set to the value of CPSR.Q on taking an exception to the current mode, and copied to CPSR.Q on executing an exception return operation in the current mode.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

`0` Taken from A32 state.

`1` Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`1` Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
`0b0000`	User
`0b0001`	FIQ
`0b0010`	IRQ
`0b0011`	Supervisor
`0b0110`	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
`0b0111`	Abort
`0b1010`	Hyp
`0b1011`	Undefined
`0b1111`	System

Other values are reserved.

Non-Confidential - Beta

G6.2.119 SPSR_abt, Saved Program Status Register (Abort mode)

The SPSR_abt characteristics are:

Purpose

Holds the saved process state when an exception is taken to Abort mode.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS, !ABT)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, !ABT)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1 (!ABT)	EL2 (NS)
-	RW	RW

Using `MRS` (banked register) and `MSR` (banked register) instructions, at PL1 this register is only accessible from PE modes other than Abort mode. In Abort mode, it is accessible as the current SPSR.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

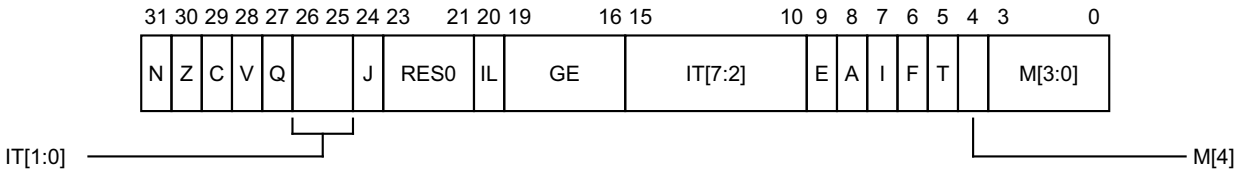
AArch32 System register SPSR_abt is architecturally mapped to AArch64 System register SPSR_abt.

Attributes

SPSR_abt is a 32-bit register.

Field descriptions

The SPSR_abt bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to Abort mode, and copied to CPSR.N on executing an exception return operation in Abort mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Abort mode, and copied to CPSR.Z on executing an exception return operation in Abort mode.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

C, bit [29]

Set to the value of CPSR.C on taking an exception to Abort mode, and copied to CPSR.C on executing an exception return operation in Abort mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Abort mode, and copied to CPSR.V on executing an exception return operation in Abort mode.

Q, bit [27]

Set to the value of CPSR.Q on taking an exception to Abort mode, and copied to CPSR.Q on executing an exception return operation in Abort mode.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

Non-Confidential - Beta

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0 Taken from A32 state.

1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1011	Undefined
0b1111	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5366.

G6.2.120 SPSR_fiq, Saved Program Status Register (FIQ mode)

The SPSR_fiq characteristics are:

Purpose

Holds the saved process state when an exception is taken to FIQ mode.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS, !FIQ)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, !FIQ)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1 (!FIQ)	EL2 (NS)
-	RW	RW

Using `MRS` (banked register) and `MSR` (banked register) instructions, at PL1 this register is only accessible from PE modes other than FIQ mode. In FIQ mode, it is accessible as the current SPSR.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

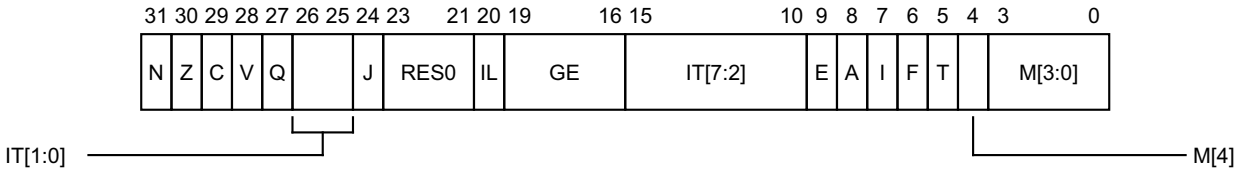
AArch32 System register SPSR_fiq is architecturally mapped to AArch64 System register SPSR_fiq.

Attributes

SPSR_fiq is a 32-bit register.

Field descriptions

The SPSR_fiq bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to FIQ mode, and copied to CPSR.N on executing an exception return operation in FIQ mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to FIQ mode, and copied to CPSR.Z on executing an exception return operation in FIQ mode.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

C, bit [29]

Set to the value of CPSR.C on taking an exception to FIQ mode, and copied to CPSR.C on executing an exception return operation in FIQ mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to FIQ mode, and copied to CPSR.V on executing an exception return operation in FIQ mode.

Q, bit [27]

Set to the value of CPSR.Q on taking an exception to FIQ mode, and copied to CPSR.Q on executing an exception return operation in FIQ mode.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

Non-Confidential - Beta

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0 Taken from A32 state.

1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1011	Undefined
0b1111	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5366.

G6.2.121 SPSR_hyp, Saved Program Status Register (Hyp mode)

The SPSR_hyp characteristics are:

Purpose

Holds the saved process state when an exception is taken to Hyp mode.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, MON)
-	-	-	-	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	-

Using `MRS` (banked register) and `MSR` (banked register) instructions, this register is only accessible from Monitor mode. In Hyp mode, this register is accessible as the current SPSR.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

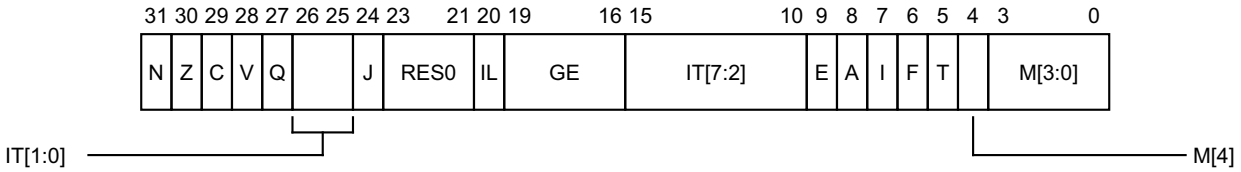
AArch32 System register SPSR_hyp is architecturally mapped to AArch64 System register SPSR_EL2.

Attributes

SPSR_hyp is a 32-bit register.

Field descriptions

The SPSR_hyp bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to Hyp mode, and copied to CPSR.N on executing an exception return operation in Hyp mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Hyp mode, and copied to CPSR.Z on executing an exception return operation in Hyp mode.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

C, bit [29]

Set to the value of CPSR.C on taking an exception to Hyp mode, and copied to CPSR.C on executing an exception return operation in Hyp mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Hyp mode, and copied to CPSR.V on executing an exception return operation in Hyp mode.

Q, bit [27]

Set to the value of CPSR.Q on taking an exception to Hyp mode, and copied to CPSR.Q on executing an exception return operation in Hyp mode.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

G6.2.122 SPSR_irq, Saved Program Status Register (IRQ mode)

The SPSR_irq characteristics are:

Purpose

Holds the saved process state when an exception is taken to IRQ mode.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS, !IRQ)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, !IRQ)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1 (!IRQ)	EL2 (NS)
-	RW	RW

Using `MRS` (banked register) and `MSR` (banked register) instructions, at PL1 this register is only accessible from PE modes other than IRQ mode. In IRQ mode, it is accessible as the current SPSR.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

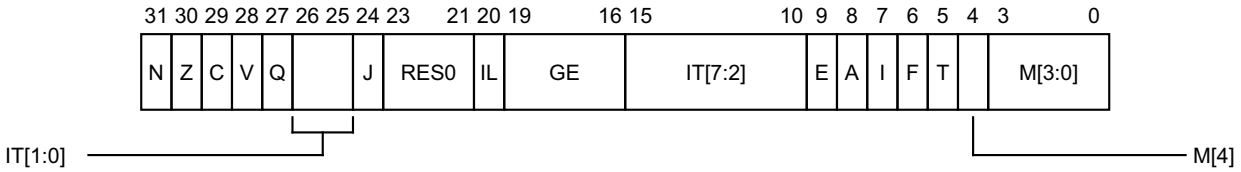
AArch32 System register SPSR_irq is architecturally mapped to AArch64 System register SPSR_irq.

Attributes

SPSR_irq is a 32-bit register.

Field descriptions

The SPSR_irq bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to IRQ mode, and copied to CPSR.N on executing an exception return operation in IRQ mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to IRQ mode, and copied to CPSR.Z on executing an exception return operation in IRQ mode.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

C, bit [29]

Set to the value of CPSR.C on taking an exception to IRQ mode, and copied to CPSR.C on executing an exception return operation in IRQ mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to IRQ mode, and copied to CPSR.V on executing an exception return operation in IRQ mode.

Q, bit [27]

Set to the value of CPSR.Q on taking an exception to IRQ mode, and copied to CPSR.Q on executing an exception return operation in IRQ mode.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

Non-Confidential - Beta

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0 Taken from A32 state.

1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1011	Undefined
0b1111	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5366.

Accessing the SPSR_irq:

To access the SPSR_irq:

```
MRS <Rd>, SPSR_irq ; Read SPSR_irq into Rd
MSR SPSR_irq, <Rd> ; Write Rd to SPSR_irq
```

G6.2.123 SPSR_mon, Saved Program Status Register (Monitor mode)

The SPSR_mon characteristics are:

Purpose

Holds the saved process state when an exception is taken to Monitor mode.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, !MON)
-	-	-	-	-	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	-

Using `MRS` (banked register) and `MSR` (banked register) instructions, this register is only accessible from EL3 modes other than Monitor mode. In Monitor mode, it is accessible as the current SPSR.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

This register is only accessible in Secure state.

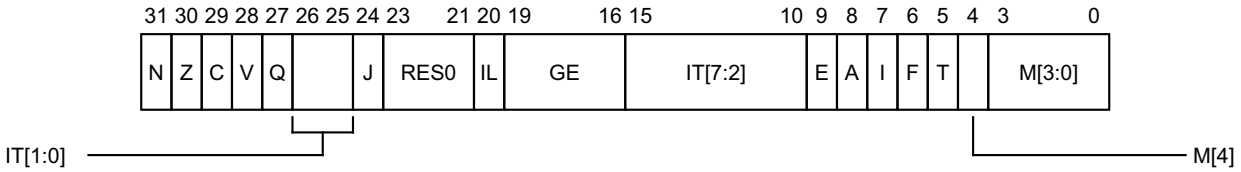
AArch32 System register SPSR_mon can be mapped to AArch64 System register SPSR_EL3, but this is not architecturally mandated.

Attributes

SPSR_mon is a 32-bit register.

Field descriptions

The SPSR_mon bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to Monitor mode, and copied to CPSR.N on executing an exception return operation in Monitor mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Monitor mode, and copied to CPSR.Z on executing an exception return operation in Monitor mode.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

C, bit [29]

Set to the value of CPSR.C on taking an exception to Monitor mode, and copied to CPSR.C on executing an exception return operation in Monitor mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Monitor mode, and copied to CPSR.V on executing an exception return operation in Monitor mode.

Q, bit [27]

Set to the value of CPSR.Q on taking an exception to Monitor mode, and copied to CPSR.Q on executing an exception return operation in Monitor mode.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0 Taken from A32 state.

1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1010	Hyp
0b1011	Undefined
0b1111	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5366.

G6.2.124 SPSR_svc, Saved Program Status Register (Sup. Call mode)

The SPSR_svc characteristics are:

Purpose

Holds the saved process state when an exception is taken to Supervisor mode.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS, !SVC)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, !SVC)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1 (!SVC)	EL2 (NS)
-	RW	RW

Using `MRS` (banked register) and `MSR` (banked register) instructions, at PL1 this register is only accessible from PE modes other than Supervisor mode. In Supervisor mode, it is accessible as the current SPSR.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

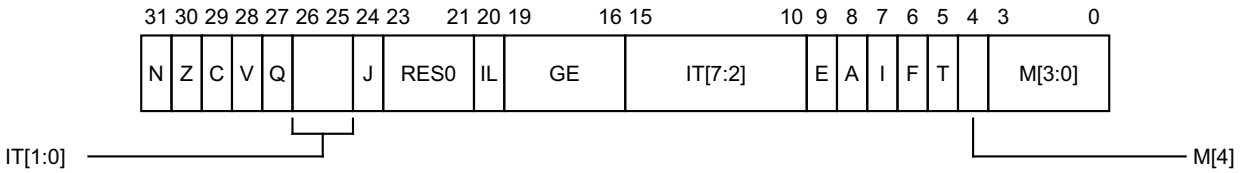
AArch32 System register SPSR_svc is architecturally mapped to AArch64 System register SPSR_EL1.

Attributes

SPSR_svc is a 32-bit register.

Field descriptions

The SPSR_svc bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to Supervisor mode, and copied to CPSR.N on executing an exception return operation in Supervisor mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Supervisor mode, and copied to CPSR.Z on executing an exception return operation in Supervisor mode.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

C, bit [29]

Set to the value of CPSR.C on taking an exception to Supervisor mode, and copied to CPSR.C on executing an exception return operation in Supervisor mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Supervisor mode, and copied to CPSR.V on executing an exception return operation in Supervisor mode.

Q, bit [27]

Set to the value of CPSR.Q on taking an exception to Supervisor mode, and copied to CPSR.Q on executing an exception return operation in Supervisor mode.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0 Taken from A32 state.

1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1011	Undefined
0b1111	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5366.

Accessing the SPSR_svc:

To access the SPSR_svc:

G6.2.125 SPSR_und, Saved Program Status Register (Undefined mode)

The SPSR_und characteristics are:

Purpose

Holds the saved process state when an exception is taken to Undefined mode.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS, !UND)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, !UND)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1 (!UND)	EL2 (NS)
-	RW	RW

Using `MRS` (banked register) and `MSR` (banked register) instructions, at PL1 this register is only accessible from PE modes other than Undefined mode. In Undefined mode, it is accessible as the current SPSR.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

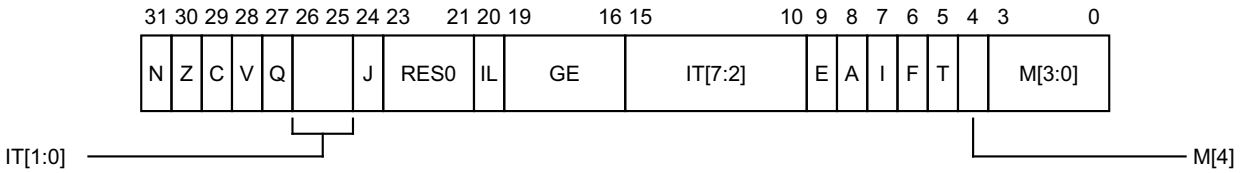
AArch32 System register SPSR_und is architecturally mapped to AArch64 System register SPSR_und.

Attributes

SPSR_und is a 32-bit register.

Field descriptions

The SPSR_und bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to Undefined mode, and copied to CPSR.N on executing an exception return operation in Undefined mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Undefined mode, and copied to CPSR.Z on executing an exception return operation in Undefined mode.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

C, bit [29]

Set to the value of CPSR.C on taking an exception to Undefined mode, and copied to CPSR.C on executing an exception return operation in Undefined mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Undefined mode, and copied to CPSR.V on executing an exception return operation in Undefined mode.

Q, bit [27]

Set to the value of CPSR.Q on taking an exception to Undefined mode, and copied to CPSR.Q on executing an exception return operation in Undefined mode.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

G6.2.126 TCMTR, TCM Type Register

The TCMTR characteristics are:

Purpose

Provides information about the implementation of the TCM.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HCR.TID1==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

If HCR_EL2.TID1==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

TCMTR is a 32-bit register.

Field descriptions

The TCMTR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the TCMTR:

To access the TCMTR:

Non-Confidential - Beta

G6.2.127 TLBIALL, TLB Invalidate All

The TLBIALL characteristics are:

Purpose

Invalidate all TLB entries for the PL1&0 translation regime, subject to the Privilege level and Security state at which the instruction is executed.

If this instruction is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

For details of the scope of this instruction see TLBIALL.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

TLBIALL is a 32-bit system operation.

Field descriptions

The TLBIALL operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBIALL operation:

To perform the TLBIALL operation:

```
MCR p15,0,<Rt>,c8,c7,0 ; TLBIALL operation, ignoring the value in Rt
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0111	000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.2.128 TLBIALLH, TLB Invalidate All, Hyp mode

The TLBIALLH characteristics are:

Purpose

Invalidate all TLB entries for the PL2 translation regime.

For details of the scope of this instruction see TLBIALLH.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	WO	WO	WO	WO-UNPREDICTABLE

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	WO

If this operation is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE. For more information see *Hyp mode TLB maintenance instructions* on page K1-5365.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

TLBIALLH is a 32-bit system operation.

Field descriptions

The TLBIALLH operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBIALLH operation:

To perform the TLBIALLH operation:

```
MCR p15,4,<Rt>,c8,c7,0 ; TLBIALLH operation, ignoring the value in Rt
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2

Non-Confidential - Beta

G6.2.129 TLBIALLHIS, TLB Invalidate All, Hyp mode, Inner Shareable

The TLBIALLHIS characteristics are:

Purpose

Invalidate all TLB entries for the PL2 translation regime, on all PEs in the same Inner Shareable domain.

For details of the scope of this instruction see TLBIALLH.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	WO	WO	WO	WO-UNPREDICTABLE

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	WO

If this operation is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE. For more information see *Hyp mode TLB maintenance instructions* on page K1-5365.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

TLBIALLHIS is a 32-bit system operation.

Field descriptions

The TLBIALLHIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBIALLHIS operation:

To perform the TLBIALLHIS operation:

```
MCR p15,4,<Rt>,c8,c3,0 ; TLBIALLHIS operation, ignoring the value in Rt
```

Non-Confidential - Beta

G6.2.130 TLBIALLIS, TLB Invalidate All, Inner Shareable

The TLBIALLIS characteristics are:

Purpose

Invalidate all TLB entries for the PL1&0 translation regime, on all PEs in the same Inner Shareable domain, subject to the Privilege level and Security state at which the instruction is executed.

If this instruction is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

For details of the scope of this instruction see TLBIALL.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

TLBIALLIS is a 32-bit system operation.

Field descriptions

The TLBIALLIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBIALLIS operation:

To perform the TLBIALLIS operation:

```
MCR p15,0,<Rt>,c8,c3,0 ; TLBIALLIS operation, ignoring the value in Rt
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0011	000

Non-Confidential - Beta

G6.2.131 TLBIALLNSNH, TLB Invalidate All, Non-Secure Non-Hyp

The TLBIALLNSNH characteristics are:

Purpose

Invalidate all TLB entries for the Non-secure PL1&0 translation regime.

For details of the scope of this instruction see TLBIALLNSNH.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	WO	WO	WO	WO-UNPREDICTABLE

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	WO

If this operation is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE. For more information see *Hyp mode TLB maintenance instructions* on page K1-5365.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

TLBIALLNSNH is a 32-bit system operation.

Field descriptions

The TLBIALLNSNH operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBIALLNSNH operation:

To perform the TLBIALLNSNH operation:

```
MCR p15,4,<Rt>,c8,c7,4 ; TLBIALLNSNH operation, ignoring the value in Rt
```

G6.2.132 TLBIALLNSNHIS, TLB Invalidate All, Non-Secure Non-Hyp, Inner Shareable

The TLBIALLNSNHIS characteristics are:

Purpose

Invalidate all TLB entries for the Non-secure PL1&0 translation regime, on all PEs in the same Inner Shareable domain.

For details of the scope of this instruction see TLBIALLNSNH.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	WO	WO	WO	WO-UNPREDICTABLE

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	WO

If this operation is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE. For more information see *Hyp mode TLB maintenance instructions* on page K1-5365.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

TLBIALLNSNHIS is a 32-bit system operation.

Field descriptions

The TLBIALLNSNHIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBIALLNSNHIS operation:

To perform the TLBIALLNSNHIS operation:

```
MCR p15,4,<Rt>,c8,c3,4 ; TLBIALLNSNHIS operation, ignoring the value in Rt
```

G6.2.133 TLBIASID, TLB Invalidate by ASID match

The TLBIASID characteristics are:

Purpose

Invalidate TLB entries for stage 1 of the PL1&0 translation regime that match the given ASID, subject to the Security state at which the instruction is executed.

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

For details of the scope of this instruction see TLBIASID.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

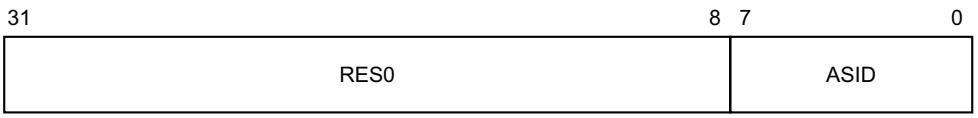
There are no configuration notes.

Attributes

TLBIASID is a 32-bit system operation.

Field descriptions

The TLBIASID input value bit assignments are:



Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.

G6.2.134 TLBIASIDIS, TLB Invalidate by ASID match, Inner Shareable

The TLBIASIDIS characteristics are:

Purpose

Invalidate TLB entries for stage 1 of the PL1&0 translation regime that match the given ASID, on all PEs in the same Inner Shareable domain, subject to the Security state at which the instruction is executed.

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

For details of the scope of this instruction see TLBIASID.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

TLBIASIDIS is a 32-bit system operation.

Field descriptions

The TLBIASIDIS input value bit assignments are:

G6.2.135 TLBIIPAS2, TLB Invalidate by Intermediate Physical Address, Stage 2

The TLBIIPAS2 characteristics are:

Purpose

Invalidate TLB entries for stage 2 of the Non-secure PL1&0 translation regime that match the given IPA and the current VMID.

For details of the scope of this instruction see TLBIIPAS2.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	WO

This instruction is a NOP when executed in Monitor mode with SCR.NS==0, and is UNPREDICTABLE when executed in any AArch32 Secure privileged mode other than Monitor mode.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIIPAS2 is a 32-bit system operation.

Field descriptions

G6.2.136 TLBIIPAS2IS, TLB Invalidate by Intermediate Physical Address, Stage 2, Inner Shareable

The TLBIIPAS2IS characteristics are:

Purpose

Invalidate TLB entries for stage 2 of the Non-secure PL1&0 translation regime that match the given IPA and the current VMID, on all PEs in the same Inner Shareable domain.

For details of the scope of this instruction see TLBIIPAS2.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	WO

This instruction is a NOP when executed in Monitor mode with SCR.NS==0, and is UNPREDICTABLE when executed in any AArch32 Secure privileged mode other than Monitor mode.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIIPAS2IS is a 32-bit system operation.

G6.2.137 TLBIIPAS2L, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level

The TLBIIPAS2L characteristics are:

Purpose

Invalidate TLB entries for stage 2 of the Non-secure PL1&0 translation regime, for the last level of translation, that match the given IPA and the current VMID.

For details of the scope of this instruction see TLBIIPAS2.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	WO

This instruction is a NOP when executed in Monitor mode with SCR.NS==0, and is UNPREDICTABLE when executed in any AArch32 Secure privileged mode other than Monitor mode.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIIPAS2L is a 32-bit system operation.

G6.2.138 TLBIIPAS2LIS, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, Inner Shareable

The TLBIIPAS2LIS characteristics are:

Purpose

Invalidate TLB entries for stage 2 of the Non-secure PL1&0 translation regime, for the last level of translation, that match the given IPA and the current VMID, on all PEs in the same Inner Shareable domain.

For details of the scope of this instruction see TLBIIPAS2L.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	WO

This instruction is a NOP when executed in Monitor mode with SCR.NS==0, and is UNPREDICTABLE when executed in any AArch32 Secure privileged mode other than Monitor mode.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIIPAS2LIS is a 32-bit system operation.

G6.2.139 TLBIMVA, TLB Invalidate by VA

The TLBIMVA characteristics are:

Purpose

Invalidate PL1&0 regime stage 1 and 2 TLB entries for the given VA and ASID, the current VMID, and the current Security state.

If this instruction is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

For details of the scope of this instruction see TLBIMVA.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

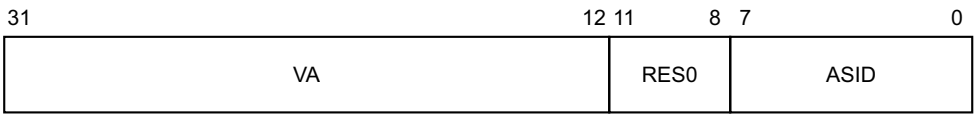
There are no configuration notes.

Attributes

TLBIMVA is a 32-bit system operation.

Field descriptions

The TLBIMVA input value bit assignments are:



Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

Performing the TLBIMVA operation:

To perform the TLBIMVA operation:

```
MCR p15,0,<Rt>,c8,c7,1 ; TLBIMVA operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0111	001

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.2.140 TLBIMVAA, TLB Invalidate by VA, All ASID

The TLBIMVAA characteristics are:

Purpose

Invalidate TLB entries for stage 1 of the PL1&0 translation regime, for any ASID, that match the given VA, subject to the Security state at which the instruction is executed.

If this instruction is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

For details of the scope of this instruction see TLBIMVAA.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

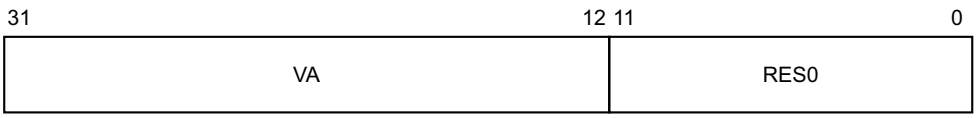
There are no configuration notes.

Attributes

TLBIMVAA is a 32-bit system operation.

Field descriptions

The TLBIMVAA input value bit assignments are:



Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

VA, bits [31:12]

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

Bits [11:0]

Reserved, RES0.

Performing the TLBIMVAA operation:

To perform the TLBIMVAA operation:

```
MCR p15,0,<Rt>,c8,c7,3 ; TLBIMVAA operation
```

The operation is encoded as follows:

G6.2.141 TLBIMVAAIS, TLB Invalidate by VA, All ASID, Inner Shareable

The TLBIMVAAIS characteristics are:

Purpose

Invalidate TLB entries for stage 1 of the PL1&0 translation regime, for any ASID, that match the given VA, on all PEs in the same Inner Shareable domain, subject to the Security state at which the instruction is executed.

If this instruction is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

For details of the scope of this instruction see TLBIMVAA.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

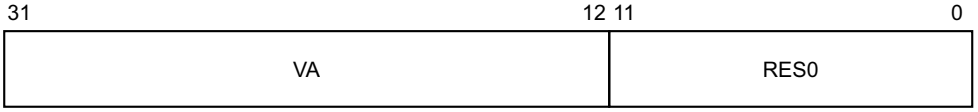
There are no configuration notes.

Attributes

TLBIMVAAIS is a 32-bit system operation.

Field descriptions

The TLBIMVAAIS input value bit assignments are:



Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

VA, bits [31:12]

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

Bits [11:0]

Reserved, RES0.

Performing the TLBIMVAAIS operation:

To perform the TLBIMVAAIS operation:

```
MCR p15,0,<Rt>,c8,c3,3 ; TLBIMVAAIS operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0011	011

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.2.142 TLBIMVAAL, TLB Invalidate by VA, All ASID, Last level

The TLBIMVAAL characteristics are:

Purpose

Invalidate TLB entries for stage 1 of the PL1&0 translation regime, for the last level of translation, for any ASID, that match the given VA, subject to the Security state at which the instruction is executed.

If this instruction is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

For details of the scope of this instruction see TLBIMVAAL.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIMVAAL is a 32-bit system operation.

Field descriptions

Non-Confidential - Beta

G6.2.143 TLBIMVAALIS, TLB Invalidate by VA, All ASID, Last level, Inner Shareable

The TLBIMVAALIS characteristics are:

Purpose

Invalidate TLB entries for stage 1 of the PL1&0 translation regime, for the last level of translation, for any ASID, that match the given VA, on all PEs in the same Inner Shareable domain, subject to the Security state at which the instruction is executed.

If this instruction is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

For details of the scope of this instruction see TLBIMVAAL.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIMVAALIS is a 32-bit system operation.

Non-Confidential - Beta

G6.2.144 TLBIMVAH, TLB Invalidate by VA, Hyp mode

The TLBIMVAH characteristics are:

Purpose

Invalidate TLB entries for the Non-secure PL2 translation regime that match the given VA.

For details of the scope of this instruction see TLBIMVAH.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	WO	WO	WO	WO-UNPREDICTABLE

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	WO

If this operation is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE. For more information see *Hyp mode TLB maintenance instructions* on page K1-5365.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

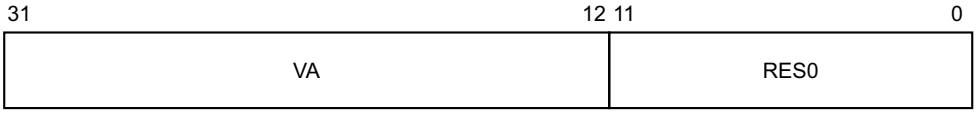
There are no configuration notes.

Attributes

TLBIMVAH is a 32-bit system operation.

Field descriptions

The TLBIMVAH input value bit assignments are:



VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Non-Confidential - Beta

G6.2.145 TLBIMVAHIS, TLB Invalidate by VA, Hyp mode, Inner Shareable

The TLBIMVAHIS characteristics are:

Purpose

Invalidate TLB entries for the Non-secure PL2 translation regime that match the given VA, on all PEs in the same Inner Shareable domain.

For details of the scope of this instruction see TLBIMVAH.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	WO	WO	WO	WO-UNPREDICTABLE

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	WO

If this operation is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE. For more information see *Hyp mode TLB maintenance instructions* on page K1-5365.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

TLBIMVAHIS is a 32-bit system operation.

G6.2.146 TLBIMVAIS, TLB Invalidate by VA, Inner Shareable

The TLBIMVAIS characteristics are:

Purpose

Invalidate TLB entries for stage 1 of the PL1&0 translation regime that match the given VA and ASID, on all PEs in the same Inner Shareable domain, subject to the Security state at which the instruction is executed.

If this instruction is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

For details of the scope of this instruction see TLBIMVA.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

TLBIMVAIS is a 32-bit system operation.

G6.2.147 TLBIMVAL, TLB Invalidate by VA, Last level

The TLBIMVAL characteristics are:

Purpose

Invalidate TLB entries for the stage 1 PL1&0 translation regime, for the last level of translation, that match the given VA and ASID, subject to the Security state at which the instruction is executed.

If this instruction is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

For details of the scope of this instruction see TLBIMVAL.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIMVAL is a 32-bit system operation.

G6.2.148 TLBIMVALH, TLB Invalidate by VA, Last level, Hyp mode

The TLBIMVALH characteristics are:

Purpose

Invalidate TLB entries for the Non-secure PL2 translation regime, for the last level of translation, that match the given VA.

For details of the scope of this instruction see TLBIMVALH.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	WO	WO	WO	WO-UNPREDICTABLE

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	WO

If this operation is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE. For more information see *Hyp mode TLB maintenance instructions* on page K1-5365.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIMVALH is a 32-bit system operation.

G6.2.149 TLBIMVALHIS, TLB Invalidate by VA, Last level, Hyp mode, Inner Shareable

The TLBIMVALHIS characteristics are:

Purpose

Invalidate TLB entries for the Non-secure PL2 translation regime, for the last level of translation, that match the given VA, on all PEs in the same Inner Shareable domain.

For details of the scope of this instruction see TLBIMVALH.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	WO	WO	WO	WO-UNPREDICTABLE

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	WO

If this operation is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE. For more information see *Hyp mode TLB maintenance instructions* on page K1-5365.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIMVALHIS is a 32-bit system operation.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.2.150 TLBIMVALIS, TLB Invalidate by VA, Last level, Inner Shareable

The TLBIMVALIS characteristics are:

Purpose

Invalidate TLB entries for stage 1 of the PL1&0 translation regime, for the last level of translation, that match the given VA and ASID, on all PEs in the same Inner Shareable domain, subject to the Security state at which the instruction is executed.

If this instruction is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

For details of the scope of this instruction see TLBIMVAL.

Usage constraints

If EL3 is implemented and is using AArch32, this operation can be performed at the following exception levels:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIMVALIS is a 32-bit system operation.

Field descriptions

The TLBIMVALIS input value bit assignments are:

G6.2.151 TLBTR, TLB Type Register

The TLBTR characteristics are:

Purpose

Provides information about the TLB implementation. The register must define whether the implementation provides separate instruction and data TLBs, or a unified TLB. Normally, the IMPLEMENTATION DEFINED information in this register includes the number of lockable entries in the TLB.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HCR.TID1==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

If HCR_EL2.TID1==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

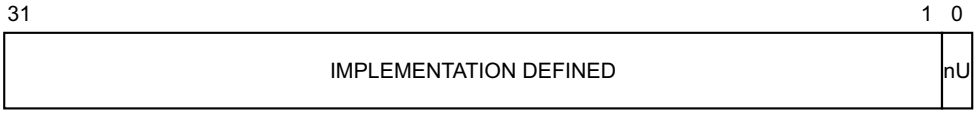
There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

TLBTR is a 32-bit register.

Field descriptions

The TLBTR bit assignments are:



IMPLEMENTATION DEFINED, bits [31:1]

IMPLEMENTATION DEFINED.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

nU, bit [0]

Not Unified TLB. Indicates whether the implementation has a unified TLB:

0 Unified TLB.

1 Separate Instruction and Data TLBs.

Accessing the TLBTR:

To access the TLBTR:

```
MRC p15,0,<Rt>,c0,c0,3 ; Read TLBTR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0000	011

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.2.152 TPIDRPRW, PL1 Software Thread ID Register

The TPIDRPRW characteristics are:

Purpose

Provides a location where software executing at EL1 or higher can store thread identifying information that is not visible to software executing at EL0, for OS management purposes.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

TPIDRPRW(S) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	-	RW

TPIDRPRW(NS) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	-

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

TPIDRPRW is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

The PE never updates this register. This means the register is always UNKNOWN on reset.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T13==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If HSTR_EL2.T13==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register TPIDRPRW is architecturally mapped to AArch64 System register TPIDR_EL1[31:0].

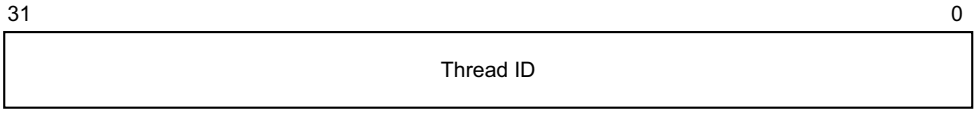
Attributes

TPIDRPRW is a 32-bit register.

Field descriptions

The TPIDRPRW bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



Bits [31:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

Accessing the TPIDRPRW:

To access the TPIDRPRW:

```
MRC p15,0,<Rt>,c13,c0,4 ; Read TPIDRPRW into Rt
MCR p15,0,<Rt>,c13,c0,4 ; Write Rt to TPIDRPRW
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1101	0000	100

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.

G6.2.153 TPIDRURO, PL0 Read-Only Software Thread ID Register

The TPIDRURO characteristics are:

Purpose

Provides a location where software executing at EL1 or higher can store thread identifying information that is visible to software executing at EL0, for OS management purposes.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

TPIDRURO(S) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	-	-	-	RW

TPIDRURO(NS) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RO	-	RW	RW	RW	-

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

TPIDRURO is accessible as follows:

EL0	EL1	EL2 (NS)
RO	RW	RW

The PE never updates this register. This means the register is always UNKNOWN on reset.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T13==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If HSTR_EL2.T13==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

Configurations

AArch32 System register TPIDRURO is architecturally mapped to AArch64 System register TPIDRRO_EL0[31:0].

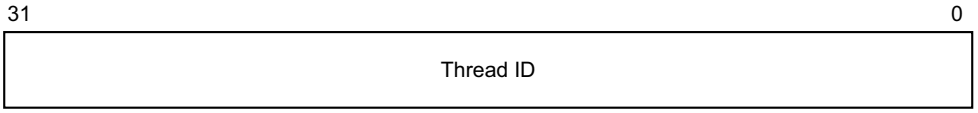
Attributes

TPIDRURO is a 32-bit register.

Field descriptions

The TPIDRURO bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



Bits [31:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

Accessing the TPIDRURO:

To access the TPIDRURO:

```
MRC p15,0,<Rt>,c13,c0,3 ; Read TPIDRURO into Rt
MCR p15,0,<Rt>,c13,c0,3 ; Write Rt to TPIDRURO
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1101	0000	011

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.

G6.2.154 TPIDRURW, PL0 Read/Write Software Thread ID Register

The TPIDRURW characteristics are:

Purpose

Provides a location where software executing at EL0 can store thread identifying information, for OS management purposes.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

TPIDRURW(S) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	-	-	-	RW

TPIDRURW(NS) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	-	RW	RW	RW	-

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

TPIDRURW is accessible as follows:

EL0	EL1	EL2 (NS)
RW	RW	RW

The PE never updates this register. This means the register is always UNKNOWN on reset.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T13==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If HSTR_EL2.T13==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

Configurations

AArch32 System register TPIDRURW is architecturally mapped to AArch64 System register TPIDR_EL0[31:0].

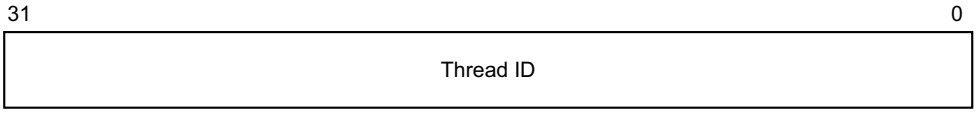
Attributes

TPIDRURW is a 32-bit register.

Field descriptions

The TPIDRURW bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



Bits [31:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

Accessing the TPIDRURW:

To access the TPIDRURW:

```
MRC p15,0,<Rt>,c13,c0,2 ; Read TPIDRURW into Rt
MCR p15,0,<Rt>,c13,c0,2 ; Write Rt to TPIDRURW
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2

G6.2.155 TTBCR, Translation Table Base Control Register

The TTBCR characteristics are:

Purpose

Determines which of the Translation Table Base Registers defines the base address for a translation table walk required for the stage 1 translation of a memory access from any mode other than Hyp mode. Also controls the translation table format and, when using the Long-descriptor translation table format, holds cacheability and shareability information.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

TTBCR(S) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	-	RW

TTBCR(NS) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	-

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

TTBCR is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.

If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.

If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

If HSTR.T2==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register TTBCR is architecturally mapped to AArch64 System register TCR_EL1[31:0].

The current translation table format determines which format of the register is used.

When EL3 is using AArch32, write access to TTBCR(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Some RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. If the PE resets into EL3 using AArch32 then:

- The EAE bit resets to 0 in both the Secure and the Non-secure instances of the register.
- Other reset values apply only to the Secure instance of the register.

Attributes

TTBCR is a 32-bit register.

Field descriptions

The TTBCR bit assignments are:

For all register layouts:

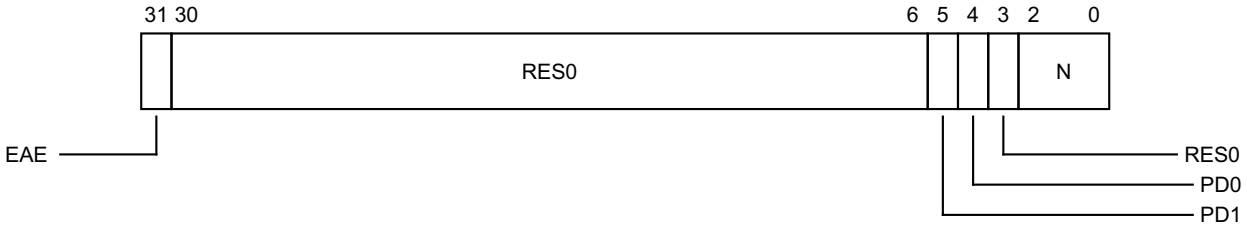
EAE, bit [31]

Extended Address Enable. The meanings of the possible values of this bit are:

`0` Use the VMSAv8-32 translation system with the Short-descriptor translation table format.

`1` Use the VMSAv8-32 translation system with the Long-descriptor translation table format.

When TTBCR.EAE==0:



EAE, bit [31]

Extended Address Enable. The meanings of the possible values of this bit are:

`0` Use the VMSAv8-32 translation system with the Short-descriptor translation table format.

When this register has an architecturally-defined reset value, this field resets to `0`.

Bits [30:6]

Reserved, RES0.

PD1, bit [5]

Translation table walk disable for translations using TTBR1. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR1. The encoding of this bit is:

`0` Perform translation table walks using TTBR1.

`1` A TLB miss on an address that is translated using TTBR1 generates a Translation fault. No translation table walk is performed.

When this register has an architecturally-defined reset value, this field resets to `0`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

PD0, bit [4]

Translation table walk disable for translations using TTBR0. This bit controls whether a translation table walk is performed on a TLB miss for an address that is translated using TTBR0. The encoding of this bit is:

`0` Perform translation table walks using TTBR0.

`1` A TLB miss on an address that is translated using TTBR0 generates a Translation fault. No translation table walk is performed.

When this register has an architecturally-defined reset value, this field resets to `0`.

Bit [3]

Reserved, RES0.

N, bits [2:0]

Indicate the width of the base address held in TTBR0. In TTBR0, the base address field is bits[31:14-N]. The value of N also determines:

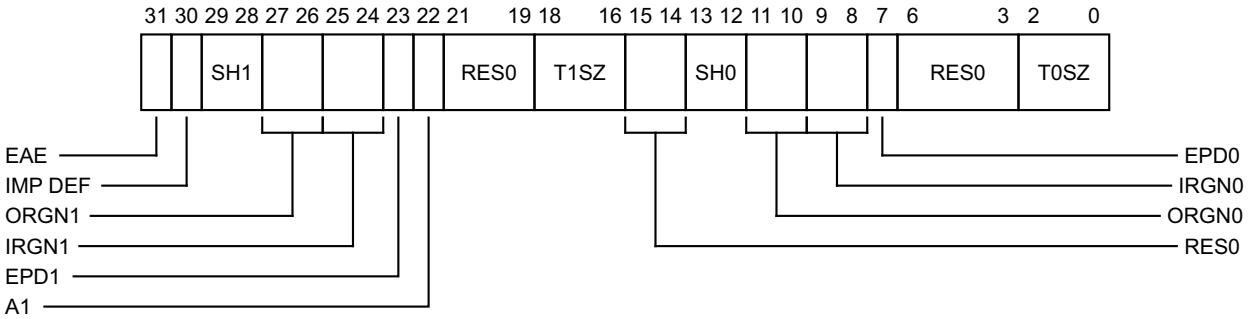
- Whether TTBR0 or TTBR1 is used as the base address for translation table walks.
- The size of the translation table pointed to by TTBR0.

N can take any value from 0 to 7, that is, from `0b000` to `0b111`.

When N has its reset value of 0, the translation table base is compatible with ARMv5 and ARMv6.

When this register has an architecturally-defined reset value, this field resets to `0`.

When TTBCR.EAE==1:



EAE, bit [31]

Extended Address Enable. The meanings of the possible values of this bit are:

`1` Use the VMSAv8-32 translation system with the Long-descriptor translation table format.

When this register has an architecturally-defined reset value, this field resets to `0`.

IMP DEF, bit [30]

IMPLEMENTATION DEFINED.

When this register has an architecturally-defined reset value, this field resets to `0`.

SH1, bits [29:28]

Shareability attribute for memory associated with translation table walks using TTBR1.

`00` Non-shareable

`10` Outer Shareable

`11` Inner Shareable

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5366.

When this register has an architecturally-defined reset value, this field resets to `0`.

ORGN1, bits [27:26]

Outer cacheability attribute for memory associated with translation table walks using TTBR1.

`00` Normal memory, Outer Non-cacheable

`01` Normal memory, Outer Write-Back Write-Allocate Cacheable

`10` Normal memory, Outer Write-Through Cacheable

`11` Normal memory, Outer Write-Back no Write-Allocate Cacheable

When this register has an architecturally-defined reset value, this field resets to `0`.

IRGN1, bits [25:24]

Inner cacheability attribute for memory associated with translation table walks using TTBR1.

`00` Normal memory, Inner Non-cacheable

`01` Normal memory, Inner Write-Back Write-Allocate Cacheable

`10` Normal memory, Inner Write-Through Cacheable

`11` Normal memory, Inner Write-Back no Write-Allocate Cacheable

When this register has an architecturally-defined reset value, this field resets to `0`.

EPD1, bit [23]

Translation table walk disable for translations using TTBR1. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR1. The encoding of this bit is:

`0` Perform translation table walks using TTBR1.

`1` A TLB miss on an address that is translated using TTBR1 generates a Translation fault. No translation table walk is performed.

When this register has an architecturally-defined reset value, this field resets to `0`.

A1, bit [22]

Selects whether TTBR0 or TTBR1 defines the ASID. The encoding of this bit is:

`0` TTBR0.ASID defines the ASID.

`1` TTBR1.ASID defines the ASID.

When this register has an architecturally-defined reset value, this field resets to `0`.

Bits [21:19]

Reserved, RES0.

T1SZ, bits [18:16]

See *Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format* on page G4-3910 for how TTBCR.{T1SZ, T0SZ} determine the input address ranges and memory region sizes translated using TTBR0 and TTBR1.

When this register has an architecturally-defined reset value, this field resets to `0`.

Bits [15:14]

Reserved, RES0.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using TTBR0.

`00` Non-shareable

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

10 Outer Shareable

11 Inner Shareable

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5366.

When this register has an architecturally-defined reset value, this field resets to 0.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using TTBR0.

00 Normal memory, Outer Non-cacheable

01 Normal memory, Outer Write-Back Write-Allocate Cacheable

10 Normal memory, Outer Write-Through Cacheable

11 Normal memory, Outer Write-Back no Write-Allocate Cacheable

When this register has an architecturally-defined reset value, this field resets to 0.

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using TTBR0.

00 Normal memory, Inner Non-cacheable

01 Normal memory, Inner Write-Back Write-Allocate Cacheable

10 Normal memory, Inner Write-Through Cacheable

11 Normal memory, Inner Write-Back no Write-Allocate Cacheable

When this register has an architecturally-defined reset value, this field resets to 0.

EPD0, bit [7]

Translation table walk disable for translations using TTBR0. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR0. The encoding of this bit is:

0 Perform translation table walks using TTBR0.

1 A TLB miss on an address that is translated using TTBR0 generates a Translation fault. No translation table walk is performed.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [6:3]

Reserved, RES0.

T0SZ, bits [2:0]

See *Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format* on page G4-3910 for how TTBCR.{T1SZ, T0SZ} determine the input address ranges and memory region sizes translated using TTBR0 and TTBR1.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the TTBCR:

To access the TTBCR:

```
MRC p15,0,<Rt>,c2,c0,2 ; Read TTBCR into Rt
MCR p15,0,<Rt>,c2,c0,2 ; Write Rt to TTBCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0010	0000	010

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.2.156 TTBR0, Translation Table Base Register 0

The TTBR0 characteristics are:

Purpose

Holds the base address of translation table 0, and information about the memory it occupies. This is one of the translation tables for the stage 1 translation of memory accesses from modes other than Hyp mode.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

TTBR0(S) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	-	RW

TTBR0(NS) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	-

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

TTBR0 is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

Used in conjunction with the TTBCR. When the 64-bit TTBR0 format is used, cacheability and shareability information is held in the TTBCR, not in TTBR0.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.

If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.

If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

If HSTR.T2==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register TTBR0 is architecturally mapped to AArch64 System register TTBR0_EL1.

TTBCR.EAE determines which TTBR0 format is used:

`EAE==0` 32-bit format is used. TTBR0[63:32] are ignored.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

EAE==1 64-bit format is used.

When EL3 is using AArch32, write access to TTBR0(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

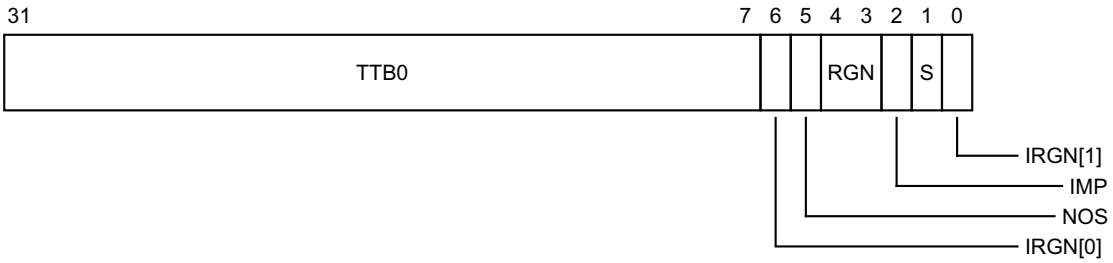
Attributes

TTBR0 is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, accesses read and write bits [31:0] and do not modify bits [63:32].

Field descriptions

The TTBR0 bit assignments are:

When TTBCR.EAE==0:



TTB0, bits [31:7]

Translation table base address, bits[31:x], where x is 14-(TTBCR.N). Register bits [x-1:7] are RES0, with the additional requirement that if these bits are not all zero, this is a misaligned Translation Table Base Address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Register bits [x-1:7] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

IRGN[0], bit [6]

See IRGN[1] below for description of the IRGN field.

NOS, bit [5]

Not Outer Shareable. When the value of TTBR0.S is 1, indicates whether the memory associated with a translation table walk is Inner Shareable or Outer Shareable:

0 Memory is Outer Shareable.

1 Memory is Inner Shareable.

This bit is ignored when the value of TTBR0.S is 0.

RGN, bits [4:3]

Region bits. Indicates the Outer cacheability attributes for the memory associated with the translation table walks:

00 Normal memory, Outer Non-cacheable.

01 Normal memory, Outer Write-Back Write-Allocate Cacheable.

10 Normal memory, Outer Write-Through Cacheable.

11 Normal memory, Outer Write-Back no Write-Allocate Cacheable.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

IMP, bit [2]

The effect of this bit is IMPLEMENTATION DEFINED. If the translation table implementation does not include any IMPLEMENTATION DEFINED features this bit is UNK/SBZP.

S, bit [1]

Shareable. Indicates whether the memory associated with the translation table walks is Non-shareable:

0 Memory is Non-shareable.

1 Memory is shareable. The TTBR0.NOS field indicates whether the memory is Inner Shareable or Outer Shareable.

IRGN[1], bit [0]

Inner region bits. Indicates the Inner Cacheability attributes for the memory associated with the translation table walks. The possible values of IRGN[1:0] are:

00 Normal memory, Inner Non-cacheable.

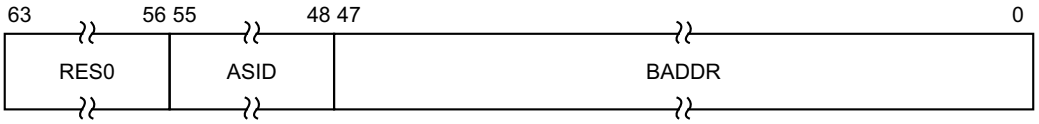
01 Normal memory, Inner Write-Back Write-Allocate Cacheable.

10 Normal memory, Inner Write-Through Cacheable.

11 Normal memory, Inner Write-Back no Write-Allocate Cacheable.

The encoding of the IRGN bits is counter-intuitive, with register bit[6] being IRGN[0] and register bit[0] being IRGN[1]. This encoding is chosen to give a consistent encoding of memory region types and to ensure that software written for ARMv7 without the Multiprocessing Extensions can run unmodified on an implementation that includes the functionality introduced by the ARMv7 Multiprocessing Extensions.

When TTBCR.EAE==1:



Bits [63:56]

Reserved, RES0.

ASID, bits [55:48]

An ASID for the translation table base address. The TTBCR.A1 field selects either TTBR0.ASID or TTBR1.ASID.

BADDR, bits [47:0]

Translation table base address, bits[47:x], Bits [x-1:0] are RES0, with the additional requirement that if bits[x-1:3] are not all zero, this is a misaligned Translation Table Base Address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

x is determined from the value of TTBCR.T0SZ as follows:

- If TTBCR.T0SZ is 0 or 1, x = 5 - TTBCR.T0SZ.
- If TTBCR.T0SZ is greater than 1, x = 14 - TTBCR.T0SZ.

If bits[47:40] of the Translation table base address are not zero, an Address size fault is generated.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the TTBR0:

To access the TTBR0 when accessing as a 32-bit register:

```
MRC p15,0,<Rt>,c2,c0,0 ; Read TTBR0[31:0] into Rt
MCR p15,0,<Rt>,c2,c0,0 ; Write Rt to TTBR0[31:0]. TTBR0[63:32] are unchanged
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0010	0000	000

To access the TTBR0 when accessing as a 64-bit register:

```
MRRC p15,0,<Rt>,<Rt2>,c2 ; Read TTBR0[31:0] into Rt and TTBR0[63:32] into Rt2
MCRR p15,0,<Rt>,<Rt2>,c2 ; Write Rt to TTBR0[31:0] and Rt2 to TTBR0[63:32]
```

Register access is encoded as follows:

Non-Confidential - Beta

G6.2.157 TTBR1, Translation Table Base Register 1

The TTBR1 characteristics are:

Purpose

Holds the base address of translation table 1, and information about the memory it occupies. This is one of the translation tables for the stage 1 translation of memory accesses from modes other than Hyp mode.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

TTBR1(S) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	-	RW

TTBR1(NS) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	-

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

TTBR1 is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

Used in conjunction with the TTBCR. When the 64-bit TTBR1 format is used, cacheability and shareability information is held in the TTBCR, not in TTBR1.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.

If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.

If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

If HSTR.T2==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register TTBR1 is architecturally mapped to AArch64 System register TTBR1_EL1.

TTBCR.EAE determines which TTBR1 format is used:

`EAE==0` 32-bit format is used. TTBR1[63:32] are ignored.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

EAE==1 64-bit format is used.

RW fields in this register reset to architecturally UNKNOWN values.

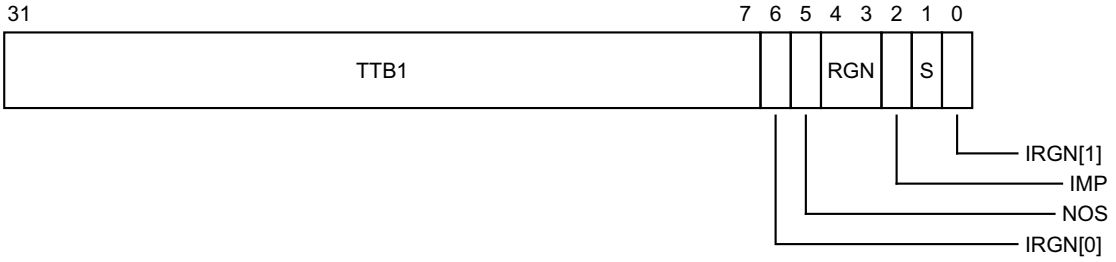
Attributes

TTBR1 is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, accesses read and write bits [31:0] and do not modify bits [63:32].

Field descriptions

The TTBR1 bit assignments are:

When TTBCR.EAE==0:



TTB1, bits [31:7]

Translation table base address, bits[31:14]. Register bits [13:7] are RES0, with the additional requirement that if these bits are not all zero, this is a misaligned Translation Table Base Address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Register bits [13:7] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

IRGN[0], bit [6]

See IRGN[1] below for description of the IRGN field.

NOS, bit [5]

Not Outer Shareable. When the value of TTBR1.S is 1, indicates whether the memory associated with a translation table walk is Inner Shareable or Outer Shareable:

0 Memory is Outer Shareable.

1 Memory is Inner Shareable.

This bit is ignored when the value of TTBR1.S is 0.

RGN, bits [4:3]

Region bits. Indicates the Outer cacheability attributes for the memory associated with the translation table walks:

00 Normal memory, Outer Non-cacheable.

01 Normal memory, Outer Write-Back Write-Allocate Cacheable.

10 Normal memory, Outer Write-Through Cacheable.

11 Normal memory, Outer Write-Back no Write-Allocate Cacheable.

IMP, bit [2]

The effect of this bit is IMPLEMENTATION DEFINED. If the translation table implementation does not include any IMPLEMENTATION DEFINED features this bit is UNK/SBZP.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

S, bit [1]

Shareable. Indicates whether the memory associated with the translation table walks is Non-shareable:

0 Memory is Non-shareable.

1 Memory is shareable. The TTBR1.NOS field indicates whether the memory is Inner Shareable or Outer Shareable.

IRGN[1], bit [0]

Inner region bits. Indicates the Inner Cacheability attributes for the memory associated with the translation table walks. The possible values of IRGN[1:0] are:

00 Normal memory, Inner Non-cacheable.

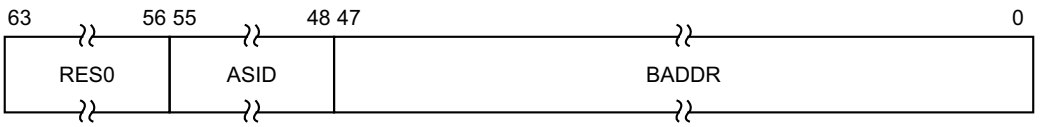
01 Normal memory, Inner Write-Back Write-Allocate Cacheable.

10 Normal memory, Inner Write-Through Cacheable.

11 Normal memory, Inner Write-Back no Write-Allocate Cacheable.

The encoding of the IRGN bits is counter-intuitive, with register bit[6] being IRGN[0] and register bit[0] being IRGN[1]. This encoding is chosen to give a consistent encoding of memory region types and to ensure that software written for ARMv7 without the Multiprocessing Extensions can run unmodified on an implementation that includes the functionality introduced by the ARMv7 Multiprocessing Extensions.

When TTBCR.EAE==1:



Bits [63:56]

Reserved, RES0.

ASID, bits [55:48]

An ASID for the translation table base address. The TTBCR.A1 field selects either TTBR0.ASID or TTBR1.ASID.

BADDR, bits [47:0]

Translation table base address, bits[47:x], Bits [x-1:0] are RES0, with the additional requirement that if bits[x-1:3] are not all zero, this is a misaligned Translation Table Base Address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

x is determined from the value of TTBCR.T1SZ as follows:

- If TTBCR.T1SZ is 0 or 1, x = 5 - TTBCR.T1SZ.
- If TTBCR.T1SZ is greater than 1, x = 14 - TTBCR.T1SZ.

If bits[47:40] of the Translation table base address are not zero, an Address size fault is generated.

Accessing the TTBR1:

To access the TTBR1 when accessing as a 32-bit register:

```
MRC p15,0,<Rt>,c2,c0,1 ; Read TTBR1[31:0] into Rt
MCR p15,0,<Rt>,c2,c0,1 ; Write Rt to TTBR1[31:0]. TTBR1[63:32] are unchanged
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0010	0000	001

To access the TTBR1 when accessing as a 64-bit register:

```
MRRC p15,1,<Rt>,<Rt2>,c2 ; Read TTBR1[31:0] into Rt and TTBR1[63:32] into Rt2
MCRR p15,1,<Rt>,<Rt2>,c2 ; Write Rt to TTBR1[31:0] and Rt2 to TTBR1[63:32]
```

Register access is encoded as follows:

1111	0001	0010

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.2.158 VBAR, Vector Base Address Register

The VBAR characteristics are:

Purpose

When high exception vectors are not selected, holds the vector base address for exceptions that are not taken to Monitor mode or to Hyp mode.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

VBAR(S) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	-	RW

VBAR(NS) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	-

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

VBAR is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

Software must program VBAR(NS) with the required initial value as part of the PE boot sequence.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T12==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If HSTR_EL2.T12==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register VBAR is architecturally mapped to AArch64 System register VBAR_EL1[31:0].

When EL3 is using AArch32, write access to VBAR(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. If the PE resets into EL3 using AArch32 they apply only to the Secure instance of the register. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

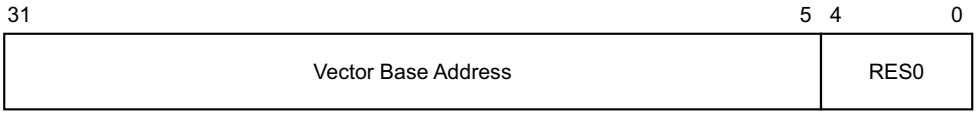
Attributes

VBAR is a 32-bit register.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Field descriptions

The VBAR bit assignments are:



Bits [31:5]

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken to this Exception level. Bits[4:0] of an exception vector are the exception offset.

When this register has an architecturally-defined reset value, this field resets to an IMPLEMENTATION DEFINED value.

Bits [4:0]

Reserved, RES0.

Accessing the VBAR:

To access the VBAR:

```
MRC p15,0,<Rt>,c12,c0,0 ; Read VBAR into Rt
MCR p15,0,<Rt>,c12,c0,0 ; Write Rt to VBAR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	0000	000

G6.2.159 VMPIDR, Virtualization Multiprocessor ID Register

The VMPIDR characteristics are:

Purpose

Holds the value of the Virtualization Multiprocessor ID. This is the value returned by Non-secure EL1 reads of MPIDR.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	-

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T0==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If HSTR_EL2.T0==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register VMPIDR is architecturally mapped to AArch64 System register VMPIDR_EL2[31:0].

If EL2 is not implemented but EL3 is implemented, this register takes the value of the MPIDR.

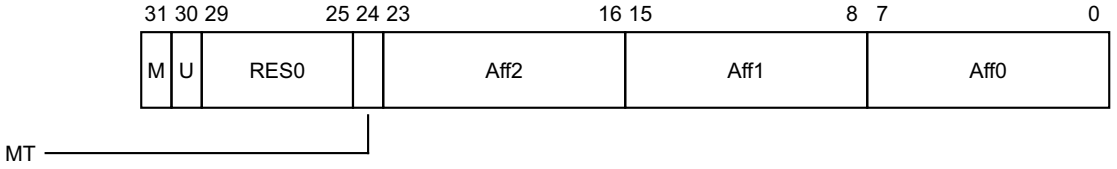
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VMPIDR is a 32-bit register.

Field descriptions

The VMPIDR bit assignments are:



Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

M, bit [31]

Indicates whether this implementation includes the functionality introduced by the ARMv7 Multiprocessing Extensions. The possible values of this bit are:

0 This implementation does not include the ARMv7 Multiprocessing Extensions functionality.

1 This implementation includes the ARMv7 Multiprocessing Extensions functionality.

In ARMv8 this bit is RES1.

U, bit [30]

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system. The possible values of this bit are:

0 Processor is part of a multiprocessor system.

1 Processor is part of a uniprocessor system.

When this register has an architecturally-defined reset value, this field resets to the value of MPIDR.U.

Bits [29:25]

Reserved, RES0.

MT, bit [24]

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. The possible values of this bit are:

0 Performance of PEs at the lowest affinity level is largely independent.

1 Performance of PEs at the lowest affinity level is very interdependent.

When this register has an architecturally-defined reset value, this field resets to the value of MPIDR.MT.

Aff2, bits [23:16]

Affinity level 2. The least significant affinity level field, for this PE in the system.

When this register has an architecturally-defined reset value, this field resets to the value of MPIDR.Aff2.

Aff1, bits [15:8]

Affinity level 1. The intermediate affinity level field, for this PE in the system.

When this register has an architecturally-defined reset value, this field resets to the value of MPIDR.Aff1.

Aff0, bits [7:0]

Affinity level 0. The most significant affinity level field, for this PE in the system.

When this register has an architecturally-defined reset value, this field resets to the value of MPIDR.Aff0.

Accessing the VMPIDR:

To access the VMPIDR:

```
MRC p15,4,<Rt>,c0,c0,5 ; Read VMPIDR into Rt
MCR p15,4,<Rt>,c0,c0,5 ; Write Rt to VMPIDR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0000	0000	101

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.2.160 VPIDR, Virtualization Processor ID Register

The VPIDR characteristics are:

Purpose

Holds the value of the Virtualization Processor ID. This is the value returned by Non-secure EL1 reads of MIDR.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	-

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T0==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If HSTR_EL2.T0==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register VPIDR is architecturally mapped to AArch64 System register VPIDR_EL2.

If EL2 is not implemented but EL3 is implemented, this register takes the value of the MIDR.

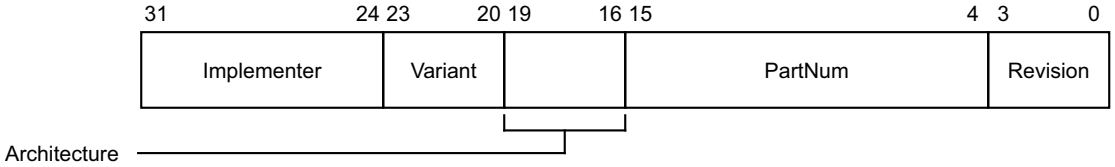
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VPIDR is a 32-bit register.

Field descriptions

The VPIDR bit assignments are:



Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by ARM. Assigned codes include the following:

Hex representation	ASCII representation	Implementer
0x41	A	ARM Limited
0x42	B	Broadcom Corporation
0x43	C	Cavium Inc.
0x44	D	Digital Equipment Corporation
0x49	I	Infineon Technologies AG
0x4D	M	Motorola or Freescale Semiconductor Inc.
0x4E	N	NVIDIA Corporation
0x50	P	Applied Micro Circuits Corporation
0x51	Q	Qualcomm Inc.
0x56	V	Marvell International Ltd.
0x69	i	Intel Corporation

ARM can assign codes that are not published in this manual. All values not assigned by ARM are reserved and must not be used.

When this register has an architecturally-defined reset value, this field resets to the value of MIDR.Implementer.

Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

When this register has an architecturally-defined reset value, this field resets to the value of MIDR.Variant.

Architecture, bits [19:16]

The permitted values of this field are:

0001 ARMv4

0010 ARMv4T

0011 ARMv5 (obsolete)

0100 ARMv5T

0101 ARMv5TE

0110 ARMv5TEJ

0111 ARMv6

1111 Architectural features are individually identified in the ID_* registers, see *Identification registers, functional group* on page G4-4048.

All other values are reserved.

When this register has an architecturally-defined reset value, this field resets to the value of MIDR.Architecture.

PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

On processors implemented by ARM, if the top four bits of the primary part number are `0x0` or `0x7`, the variant and architecture are encoded differently.

When this register has an architecturally-defined reset value, this field resets to the value of MIDR.PartNum.

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

When this register has an architecturally-defined reset value, this field resets to the value of MIDR.Revision.

Accessing the VPIDR:

To access the VPIDR:

```
MRC p15,4,<Rt>,c0,c0,0 ; Read VPIDR into Rt
MCR p15,4,<Rt>,c0,c0,0 ; Write Rt to VPIDR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0000	0000	000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.2.161 VTCR, Virtualization Translation Control Register

The VTCR characteristics are:

Purpose

Controls the translation table walks required for the stage 2 translation of memory accesses from Non-secure modes other than Hyp mode, and holds cacheability and shareability information for the accesses.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	-

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	RW

Used in conjunction with VTTBR, that defines the translation table base address for the translations.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T2==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register VTCR is architecturally mapped to AArch64 System register VTCR_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

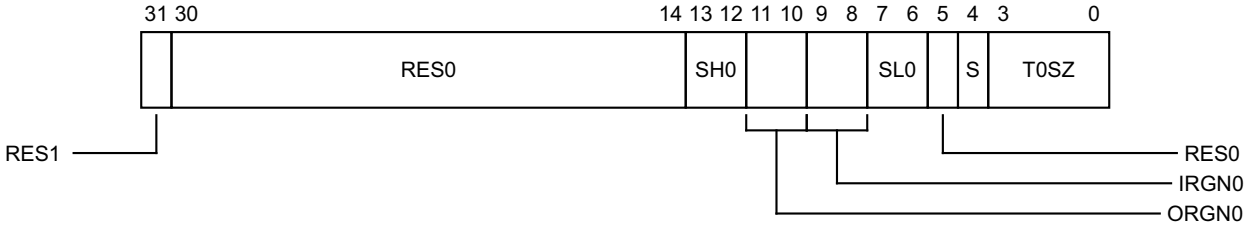
Attributes

VTCR is a 32-bit register.

Field descriptions

The VTCR bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



Bit [31]

Reserved, RES1.

Bits [30:14]

Reserved, RES0.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using VTTBR.

`00` Non-shareable

`10` Outer Shareable

`11` Inner Shareable

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5366.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using VTTBR.

`00` Normal memory, Outer Non-cacheable

`01` Normal memory, Outer Write-Back Write-Allocate Cacheable

`10` Normal memory, Outer Write-Through Cacheable

`11` Normal memory, Outer Write-Back no Write-Allocate Cacheable

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using VTTBR.

`00` Normal memory, Inner Non-cacheable

`01` Normal memory, Inner Write-Back Write-Allocate Cacheable

`10` Normal memory, Inner Write-Through Cacheable

`11` Normal memory, Inner Write-Back no Write-Allocate Cacheable

SL0, bits [7:6]

Starting level for translation table walks using VTTBR.

`00` Start at level 2

`01` Start at level 1

All other values are reserved. The effect of programming this field to a reserved value, or to a value that is not consistent with the programming of T0SZ, is that behavior is CONSTRAINED UNPREDICTABLE, as described in *CONSTRAINED UNPREDICTABLE combinations of the starting level and size fields* on page K1-5363.

Bit [5]

Reserved, RES0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

S, bit [4]

Sign extension bit. This bit must be programmed to the value of T0SZ[3]. If it is not, then the behavior is CONSTRAINED UNPREDICTABLE and the stage 2 T0SZ value is treated as an UNKNOWN value, see *Misprogramming VTCR.S* on page K1-5362.

T0SZ, bits [3:0]

The size offset of the memory region addressed by VTTBR. The region size is $2^{(32-T0SZ)}$ bytes.

This field holds a four-bit signed integer value, meaning it supports values from -8 to 7.

Note

This is different from the other translation control registers, where TnSZ holds a three-bit unsigned integer, supporting values from 0 to 7.

The effect of programming this field to a value that is not consistent with the programming of SL0, is that behavior is CONSTRAINED UNPREDICTABLE, as described in *CONSTRAINED UNPREDICTABLE combinations of the starting level and size fields* on page K1-5363.

Accessing the VTCR:

To access the VTCR:

```
MRC p15,4,<Rt>,c2,c1,2 ; Read VTCR into Rt
MCR p15,4,<Rt>,c2,c1,2 ; Write Rt to VTCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0010	0001	010

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.2.162 VTTBR, Virtualization Translation Table Base Register

The VTTBR characteristics are:

Purpose

Holds the base address of the translation table for the stage 2 translation of memory accesses from Non-secure modes other than Hyp mode.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	-

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	RW

Used in conjunction with the VTCR.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T2==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register VTTBR is architecturally mapped to AArch64 System register VTTBR_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

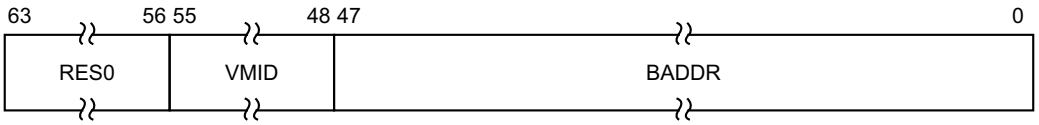
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VTTBR is a 64-bit register.

Field descriptions

The VTTBR bit assignments are:



Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Bits [63:56]

Reserved, RES0.

VMID, bits [55:48]

The VMID for the translation table.

When this register has an architecturally-defined reset value, this field resets to `0`.

BADDR, bits [47:0]

Translation table base address, bits[47:x], Bits [x-1:0] are RES0, with the additional requirement that if bits[x-1:3] are not all zero, this is a misaligned Translation Table Base Address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

x is determined from the value of VTCR.T0SZ as follows:

- If VTCR.T0SZ is 0 or 1, x = 5 - VTCR.T0SZ.
- If VTCR.T0SZ is greater than 1, x = 14 - VTCR.T0SZ.

If bits[47:40] of the Translation table base address are not zero, an Address size fault is generated.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the VTTBR:

To access the VTTBR:

```
MRRC p15,6,<Rt>,<Rt2>,c2 ; Read VTTBR[31:0] into Rt and VTTBR[63:32] into Rt2
MCRR p15,6,<Rt>,<Rt2>,c2 ; Write Rt to VTTBR[31:0] and Rt2 to VTTBR[63:32]
```

Register access is encoded as follows:

G6.3 Debug registers

This section lists the Debug System registers in AArch32 state, in alphabetic order.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.1 DBGAUTHSTATUS, Debug Authentication Status register

The DBGAUTHSTATUS characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TDA==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, read accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGAUTHSTATUS is architecturally mapped to AArch64 System register DBGAUTHSTATUS_EL1.

AArch32 System register DBGAUTHSTATUS is architecturally mapped to External register DBGAUTHSTATUS_EL1.

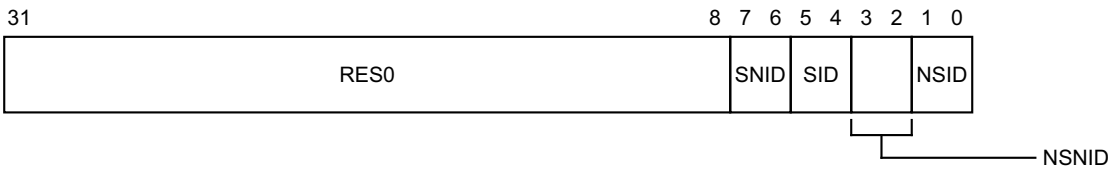
This register is required in all implementations.

Attributes

DBGAUTHSTATUS is a 32-bit register.

Field descriptions

The DBGAUTHSTATUS bit assignments are:



Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Bits [31:8]

Reserved, RES0.

SNID, bits [7:6]

Secure non-invasive debug. Possible values of this field are:

00 Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state.

10 Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.

11 Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.

SID, bits [5:4]

Secure invasive debug. Possible values of this field are:

00 Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state.

10 Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.

11 Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.

Other values are reserved.

NSNID, bits [3:2]

Non-secure non-invasive debug. Possible values of this field are:

00 Not implemented. EL3 is not implemented and the implemented Security state is Secure state.

10 Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.

11 Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.

NSID, bits [1:0]

Non-secure invasive debug. Possible values of this field are:

00 Not implemented. EL3 is not implemented and the implemented Security state is Secure state.

10 Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.

11 Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

Other values are reserved.

Accessing the DBGAUTHSTATUS:

To access the DBGAUTHSTATUS:

```
MRC p14,0,<Rt>,c7,c14,6 ; Read DBGAUTHSTATUS into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0111	1110	110

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.2 DBGBCR<n>, Debug Breakpoint Control Registers, n = 0 - 15

The DBGBCR<n> characteristics are:

Purpose

Holds control information for a breakpoint. Forms breakpoint n together with value register DBGBVR<n>. If EL2 is implemented and this breakpoint supports Context matching, DBGBVR<n> can be associated with a Breakpoint Extended Value Register DBGBXVR<n> for VMID matching.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

When the E field is zero, all the other fields in the register are ignored.

Traps and Enables

For a description of the prioritization of any generated exceptions, see:

- *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state.
- *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.
- *Software Access debug event* on page H3-4753 for accesses to this register taken to Debug state.

Subject to the prioritization rules:

If EDSCR.TDA==1, DBGOSLSR.OSLK==0, and halting is allowed, EL1, EL2, and EL3 accesses to this register generate a Software Access debug event.

If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGBCR<n> is architecturally mapped to AArch64 System register DBGBCR<n>_EL1.

AArch32 System register DBGBCR<n> is architecturally mapped to External register DBGBCR<n>_EL1.

If breakpoint n is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

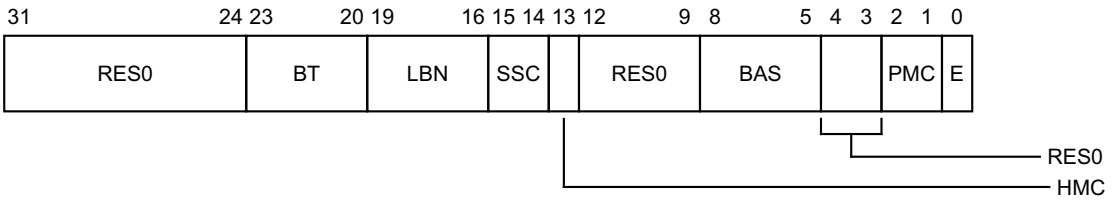
Attributes

DBGBCR<n> is a 32-bit register.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Field descriptions

The DBGBCR<n> bit assignments are:



Bits [31:24]

Reserved, RES0.

BT, bits [23:20]

Breakpoint Type. Possible values are:

`0000` Unlinked instruction address match.

`0001` Linked instruction address match.

`0010` Unlinked context ID match.

`0011` Linked context ID match

`0100` Unlinked instruction address mismatch.

`0101` Linked instruction address mismatch.

`1000` Unlinked VMID match.

`1001` Linked VMID match.

`1010` Unlinked VMID and context ID match.

`1011` Linked VMID and context ID match.

The field breaks down as follows:

- BT[3:1]: Base type.

  `000` Match address. DBGBVR<n> is the address of an instruction.

  `010` Mismatch address. DBGBVR<n> is the address of an instruction to be stepped.

  `001` Match context ID. DBGBVR<n> is a context ID.

  `100` Match VMID. DBGBXVR<n>.VMID is a VMID.

  `101` Match VMID and context ID. DBGBVR<n> is a context ID, and DBGBXVR<n>.VMID is a VMID.

- BT[0]: Enable linking.

All other values are reserved. Constraints on breakpoint programming mean other values are reserved under some conditions. For more information, including the effect of programming this field to a reserved value, see *Reserved DBGBCR<n>.BT values* on page G2-3811.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

LBN, bits [19:16]

Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.

For all other breakpoint types this field is ignored and reads of the register return an UNKNOWN value.

This field is ignored when the value of DBGBCR<n>.E is 0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

SSC, bits [15:14]

Security state control. Determines the Security states under which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the HMC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information, including the effect of programming the fields to a reserved set of values, see *Usage constraints* on page G2-3811.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see the SSC, bits [15:14] description.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bits [12:9]

Reserved, RES0.

BAS, bits [8:5]

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and Execution state. In an AArch64-only implementation, this field is reserved, RES1. Otherwise:

- BAS[2] and BAS[0] are read/write.
- BAS[3] and BAS[1] are read-only copies of BAS[2] and BAS[0] respectively.

The values `0011` and `1100` are only supported if AArch32 is supported at any Exception level.

The permitted values depend on the breakpoint type.

For Address match breakpoints, the permitted values are:

BAS	Match instruction at	Constraint for debuggers
`0011`	DBGBVR<n>	Use for T32 instructions.
`1100`	DBGBVR<n>+2	Use for T32 instructions.
`1111`	DBGBVR<n>	Use for A32 instructions.

`0000` is reserved and must behave as if the breakpoint is disabled or map to a permitted value.

For more information, see *Using the BAS field in Address Match breakpoints* on page G2-3805.

For Address mismatch breakpoints in an AArch32 stage 1 translation regime, the permitted values are:

BAS	Step instruction at	Constraint for debuggers
`0000`	-	Use for a match anywhere breakpoint.
`0011`	DBGBVR<n>	Use for stepping T32 instructions.
`1100`	DBGBVR<n>+2	Use for stepping T32 instructions.
`1111`	DBGBVR<n>	Use for stepping A32 instructions.

For more information, see *Using the BAS field in Address Match breakpoints* on page G2-3805.

For Context matching breakpoints, this field is RES1 and ignored.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bits [4:3]

Reserved, RES0.

PMC, bits [2:1]

Privilege mode control. Determines the Exception level or levels at which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see the DBGBCR<n>.SSC description.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

E, bit [0]

Enable breakpoint DBGBVR<n>. Possible values are:

`0` Breakpoint disabled.

`1` Breakpoint enabled.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the DBGBCR<n>:

To access the DBGBCR<n>:

```
MRC p14,0,<Rt>,c0,<CRm>,5 ; Read DBGBCR<n> into Rt, where n is in the range 0 to 15
MCR p14,0,<Rt>,c0,<CRm>,5 ; Write Rt to DBGBCR<n>, where n is in the range 0 to 15
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	n<3:0>	101

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.3 DBGBVR<n>, Debug Breakpoint Value Registers, n = 0 - 15

The DBGBVR<n> characteristics are:

Purpose

Holds a value for use in breakpoint matching, either the virtual address of an instruction or a context ID. Forms breakpoint n together with control register DBGBCR<n>. If EL2 is implemented and this breakpoint supports Context matching, DBGBVR<n> can be associated with a Breakpoint Extended Value Register DBGBXVR<n> for VMID matching.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

Some breakpoints might not support Context ID comparison. For more information, see the description of the DBGDIDR.CTX_CMPs field.

Traps and Enables

For a description of the prioritization of any generated exceptions, see:

- *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state.
- *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.
- *Software Access debug event* on page H3-4753 for accesses to this register taken to Debug state.

Subject to the prioritization rules:

If EDSCR.TDA==1, DBGOSLSR.OSLK==0, and halting is allowed, EL1, EL2, and EL3 accesses to this register generate a Software Access debug event.

If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGBVR<n> is architecturally mapped to AArch64 System register DBGBVR<n>_EL1[31:0].

Note

Writes to DBGBVR<n> do not modify DBGBVR<n>_EL1[63:32].

AArch32 System register DBGBVR<n> is architecturally mapped to External register DBGBVR<n>_EL1[31:0].

If breakpoint n is not implemented then this register is unallocated.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes

How this register is interpreted depends on the value of DBGBCR<n>.BT.

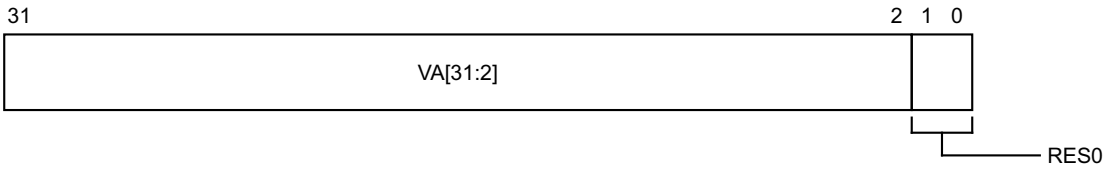
- When DBGBCR<n>.BT is 0b0x0x, this register holds a virtual address.
- When DBGBCR<n>.BT is 0b001x or 0b101x, this register holds a Context ID.

For other values of DBGBCR<n>.BT, this register is RES0.

Field descriptions

The DBGBVR<n> bit assignments are:

When DBGBCR<n>.BT==0b0x0x:



VA[31:2], bits [31:2]

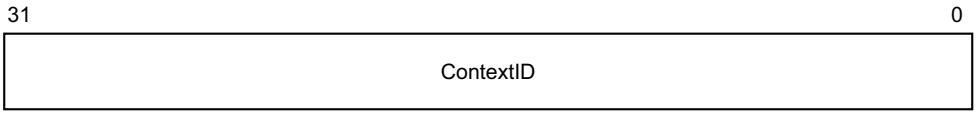
Bits[31:2] of the address value for comparison.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bits [1:0]

Reserved, RES0.

When DBGBCR<n>.BT==0b001x:

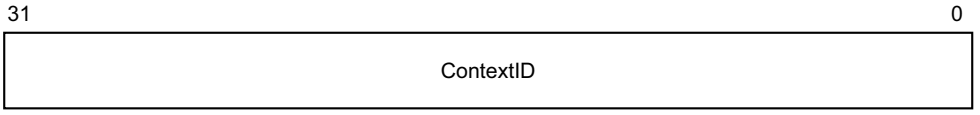


ContextID, bits [31:0]

Context ID value for comparison.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

When DBGBCR<n>.BT==0b101x and EL2 implemented:



ContextID, bits [31:0]

Context ID value for comparison.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the DBGBVR<n>:

To access the DBGBVR<n>:

```
MRC p14,0,<Rt>,c0,<CRm>,4 ; Read DBGBVR<n> into Rt, where n is in the range 0 to 15
MCR p14,0,<Rt>,c0,<CRm>,4 ; Write Rt to DBGBVR<n>, where n is in the range 0 to 15
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	n<3:0>	100

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.4 DBGBXVR<n>, Debug Breakpoint Extended Value Registers, n = 0 - 15

The DBGBXVR<n> characteristics are:

Purpose

Holds a value for use in breakpoint matching, to support VMID matching. Used in conjunction with a control register DBGBCR<n> and a value register DBGBVR<n>, where EL2 is implemented and breakpoint n supports Context matching.

Usage constraints

DBGBXVR<n> is implemented only if the implementation includes EL2 and the breakpoint supports Context matching. Otherwise it is unallocated.

When DBGBXVR<n> is implemented, if EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW

When DBGBXVR<n> is implemented, if EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

DBGBXVR<n> is implemented only if the implementation includes EL2 and the breakpoint supports Context ID matching. Otherwise it is unallocated. For more information, see the description of the DBGDIDR.CTX_CMPs field.

Traps and Enables

For a description of the prioritization of any generated exceptions, see:

- *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state.
- *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.
- *Software Access debug event* on page H3-4753 for accesses to this register taken to Debug state.

Subject to the prioritization rules:

If EDSCR.TDA==1, DBGOSLSR.OSLK==0, and halting is allowed, EL1, EL2, and EL3 accesses to this register generate a Software Access debug event.

If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

When DBGBXVR<n> is implemented, there is one instance of the register that is used in both Secure and Non-secure states.

AArch32 System register DBGBXVR<n> is architecturally mapped to AArch64 System register DBGBVR<n>_EL1[63:32].

Note

Writes to DBGBXVR<n> do not modify DBGBVR<n>_EL1[31:0].

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

AArch32 System register DBGBXVR<n> is architecturally mapped to External register DBGBVR<n>_EL1[63:32].

This register is unallocated in any of the following cases:

- Breakpoint n is not implemented.
- Breakpoint n does not support Context matching.
- EL2 is not implemented.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

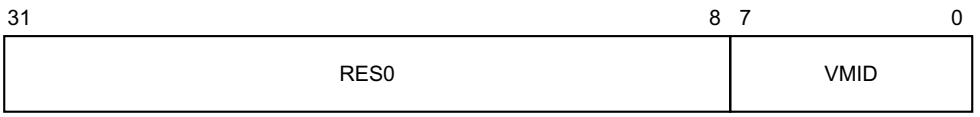
Attributes

When DBGBCR<n>.BT is 0b10xx, this register holds a VMID. For other values of DBGBCR<n>.BT, this register is RES0.

Field descriptions

The DBGBXVR<n> bit assignments are:

When DBGBCR<n>.BT==0b10xx and EL2 implemented:



Bits [31:8]

Reserved, RES0.

VMID, bits [7:0]

VMID value for comparison.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the DBGBXVR<n>:

To access the DBGBXVR<n>:

```
MRC p14,0,<Rt>,c1,<CRm>,1 ; Read DBGBXVR<n> into Rt, where n is in the range 0 to 15
MCR p14,0,<Rt>,c1,<CRm>,1 ; Write Rt to DBGBXVR<n>, where n is in the range 0 to 15
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0001	n<3:0>	001

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.5 DBGCLAIMCLR, Debug Claim Tag Clear register

The DBGCLAIMCLR characteristics are:

Purpose

Used by software to read the values of the CLAIM tag bits, and to clear these bits to 0.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

The architecture does not define any functionality for the CLAIM tag bits.

Note

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the DBGCLAIMSET register.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGCLAIMCLR is architecturally mapped to AArch64 System register DBGCLAIMCLR_EL1.

AArch32 System register DBGCLAIMCLR is architecturally mapped to External register DBGCLAIMCLR_EL1.

An implementation must include 8 CLAIM tag bits.

This register is in the Cold reset domain. See the CLAIM field description for the effect of a Cold reset on the value returned by this register. This register is not affected by a Warm reset.

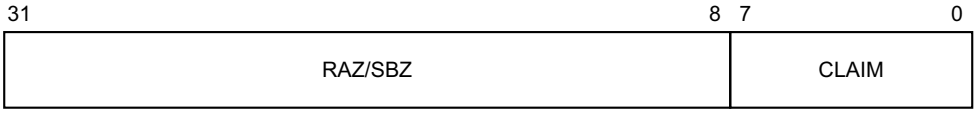
Attributes

DBGCLAIMCLR is a 32-bit register.

Field descriptions

The DBGCLAIMCLR bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Read or clear CLAIM tag bits. Reading this field returns the current value of the CLAIM tag bits.

Writing a 1 to one of these bits clears the corresponding CLAIM tag bit to 0. This is an indirect write to the CLAIM tag bits. A single write operation can clear multiple CLAIM tag bits to 0.

Writing 0 to one of these bits has no effect.

A cold reset clears the CLAIM tag bits to 0.

Accessing the DBGCLAIMCLR:

To access the DBGCLAIMCLR:

```
MRC p14,0,<Rt>,c7,c9,6 ; Read DBGCLAIMCLR into Rt
MCR p14,0,<Rt>,c7,c9,6 ; Write Rt to DBGCLAIMCLR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0111	1001	110

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.6 DBGCLAIMSET, Debug Claim Tag Set register

The DBGCLAIMSET characteristics are:

Purpose

Used by software to set the CLAIM tag bits to 1.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

The architecture does not define any functionality for the CLAIM tag bits.

Note

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the DBGCLAIMCLR register.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGCLAIMSET is architecturally mapped to AArch64 System register DBGCLAIMSET_EL1.

AArch32 System register DBGCLAIMSET is architecturally mapped to External register DBGCLAIMSET_EL1.

An implementation must include 8 CLAIM tag bits.

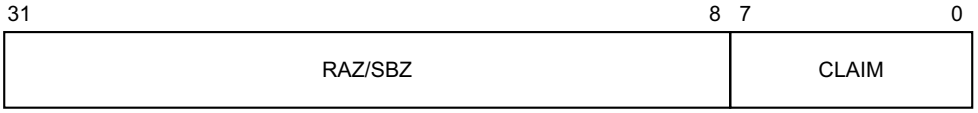
Attributes

DBGCLAIMSET is a 32-bit register.

Field descriptions

The DBGCLAIMSET bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Set CLAIM tag bits. RAO.

Writing a 1 to one of these bits sets the corresponding CLAIM tag bit to 1. This is an indirect write to the CLAIM tag bits. A single write operation can set multiple CLAIM tag bits to 1.

Writing 0 to one of these bits has no effect.

A cold reset clears the CLAIM tag bits to 0.

Accessing the DBGCLAIMSET:

To access the DBGCLAIMSET:

```
MRC p14,0,<Rt>,c7,c8,6 ; Read DBGCLAIMSET into Rt
MCR p14,0,<Rt>,c7,c8,6 ; Write Rt to DBGCLAIMSET
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0111	1000	110

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.7 DBGDCCINT, DCC Interrupt Enable Register

The DBGDCCINT characteristics are:

Purpose

Enables interrupt requests to be signaled based on the DCC status flags.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGDCCINT is architecturally mapped to AArch64 System register MDCCINT_EL1.

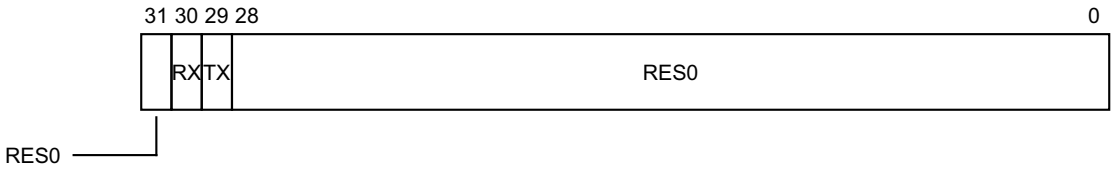
This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DBGDCCINT is a 32-bit register.

Field descriptions

The DBGDCCINT bit assignments are:



Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Bit [31]

Reserved, RES0.

RX, bit [30]

DCC interrupt request enable control for DTRRX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.

`0` No interrupt request generated by DTRRX.

`1` Interrupt request will be generated on RXfull == 1.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

When this register has an architecturally-defined reset value, this field resets to `0`.

TX, bit [29]

DCC interrupt request enable control for DTRTX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.

`0` No interrupt request generated by DTRTX.

`1` Interrupt request will be generated on TXfull == 0.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

When this register has an architecturally-defined reset value, this field resets to `0`.

Bits [28:0]

Reserved, RES0.

Accessing the DBGDCCINT:

To access the DBGDCCINT:

```
MRC p14,0,<Rt>,c0,c2,0 ; Read DBGDCCINT into Rt
MCR p14,0,<Rt>,c0,c2,0 ; Write Rt to DBGDCCINT
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0010	000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.8 DBGDEVID, Debug Device ID register 0

The DBGDEVID characteristics are:

Purpose

Adds to the information given by the DBGDIDR by describing other features of the debug implementation.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TDA==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, read accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

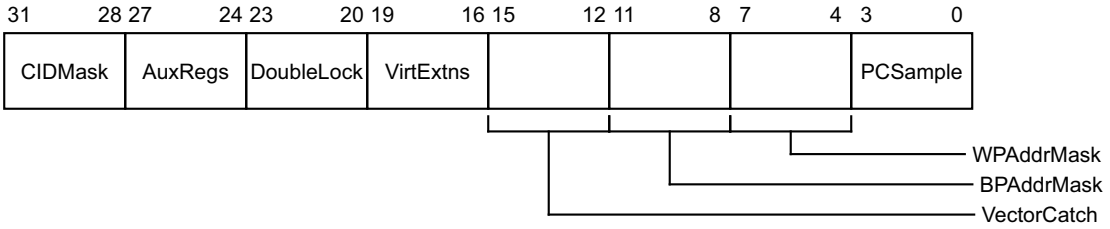
This register is required in all implementations.

Attributes

DBGDEVID is a 32-bit register.

Field descriptions

The DBGDEVID bit assignments are:



Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

CIDMask, bits [31:28]

Indicates the level of support for the Context ID matching breakpoint masking capability. Permitted values of this field are:

0000 Context ID masking is not implemented.

0001 Context ID masking is implemented.

All other values are reserved. The value of this for ARMv8 is 0000.

AuxRegs, bits [27:24]

Indicates support for Auxiliary registers. Permitted values for this field are:

0000 None supported.

0001 Support for External Debug Auxiliary Control Register, EDACR.

All other values are reserved.

DoubleLock, bits [23:20]

Indicates the presence of the DBGOSDLR, OS Double Lock Register. Permitted values of this field are:

0000 The DBGOSDLR is not present.

0001 The DBGOSDLR is present.

All other values are reserved. The value of this for ARMv8 is 0001.

VirtExtns, bits [19:16]

Indicates whether EL2 is implemented. Permitted values of this field are:

0000 EL2 is not implemented.

0001 EL2 is implemented.

All other values are reserved.

VectorCatch, bits [15:12]

Defines the form of Vector catch debug event implemented. Permitted values of this field are:

0000 Address matching vector catch debug event implemented.

0001 Exception matching vector catch debug event implemented.

All other values are reserved.

BPAddrMask, bits [11:8]

Indicates the level of support for the instruction address matching breakpoint masking capability. Permitted values of this field are:

0000 Breakpoint address masking might be implemented. If not implemented, DBGBCR<n>[28:24] is RAZ/WI.

0001 Breakpoint address masking is implemented.

1111 Breakpoint address masking is not implemented. DBGBCR<n>[28:24] is RES0.

All other values are reserved. The value of this for ARMv8 is 1111.

WPAddrMask, bits [7:4]

Indicates the level of support for the data address matching watchpoint masking capability. Permitted values of this field are:

0000 Watchpoint address masking might be implemented. If not implemented, DBGWCR<n>.MASK (Address mask) is RAZ/WI.

0001 Watchpoint address masking is implemented.

1111 Watchpoint address masking is not implemented. DBGWCR<n>.MASK (Address mask) is RES0.

All other values are reserved. The value of this for ARMv8 is 0001.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

PCSample, bits [3:0]

Indicates the level of Sample-based profiling support using external debug registers 40 through 43. Permitted values of this field in ARMv8 are:

`0000` Architecture-defined form of Sample-based profiling not implemented.

`0010` EDPCSR and EDCIDSR are implemented (only permitted if EL3 and EL2 are not implemented).

`0011` EDPCSR, EDCIDSR, and EDVIDSR are implemented.

All other values are reserved.

Accessing the DBGDEVID:

To access the DBGDEVID:

```
MRC p14,0,<Rt>,c7,c2,7 ; Read DBGDEVID into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0111	0010	111

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.9 DBGDEVID1, Debug Device ID register 1

The DBGDEVID1 characteristics are:

Purpose

Adds to the information given by the DBGDIDR by describing other features of the debug implementation.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TDA==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, read accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

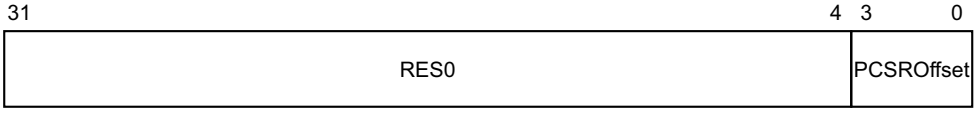
This register is required in all implementations.

Attributes

DBGDEVID1 is a 32-bit register.

Field descriptions

The DBGDEVID1 bit assignments are:



Bits [31:4]

Reserved, RES0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

PCSROffset, bits [3:0]

This field indicates the offset applied to PC samples returned by reads of EDPCSR. Permitted values of this field in ARMv8 are:

`0000` EDPCSR not implemented.

`0010` EDPCSR implemented. Samples have no offset applied and do not sample the instruction set state in AArch32 state.

Note

In ARMv7, a PCSROffset value of `0000` has an alternative meaning that EDPCSR is implemented and returns values that have an offset applied and indicate the Instruction set state. This implementation option is not permitted in ARMv8.

Accessing the DBGDEVID1:

To access the DBGDEVID1:

```
MRC p14,0,<Rt>,c7,c1,7 ; Read DBGDEVID1 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0111	0001	111

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.10 DBGDEVID2, Debug Device ID register 2

The DBGDEVID2 characteristics are:

Purpose

Reserved for future descriptions of features of the debug implementation.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TDA==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, read accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

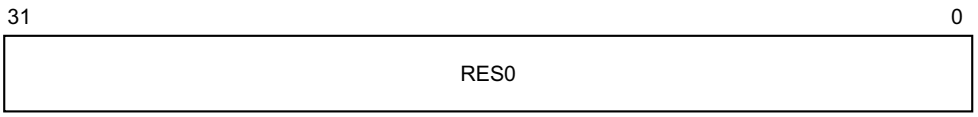
There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

DBGDEVID2 is a 32-bit register.

Field descriptions

The DBGDEVID2 bit assignments are:



Bits [31:0]

Reserved, RES0.

Accessing the DBGDEVID2:

To access the DBGDEVID2:

```
MRC p14,0,<Rt>,c7,c0,7 ; Read DBGDEVID2 into Rt
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0111	0000	111

Non-Confidential - Beta

G6.3.11 DBGDIDR, Debug ID Register

The DBGDIDR characteristics are:

Purpose

Specifies which version of the Debug architecture is implemented, and some features of the debug implementation.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RO	RO	RO

ARM deprecates any access to this register from EL0.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If DBGDSCRext.UDCCdis==1, read accesses to this register from PL0 are trapped to Undefined mode.

If HDCR.TDA==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, read accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If MDSCR_EL1.TDCC==1, read accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

If EL1 cannot use AArch32 then the implementation of this register is OPTIONAL and deprecated.

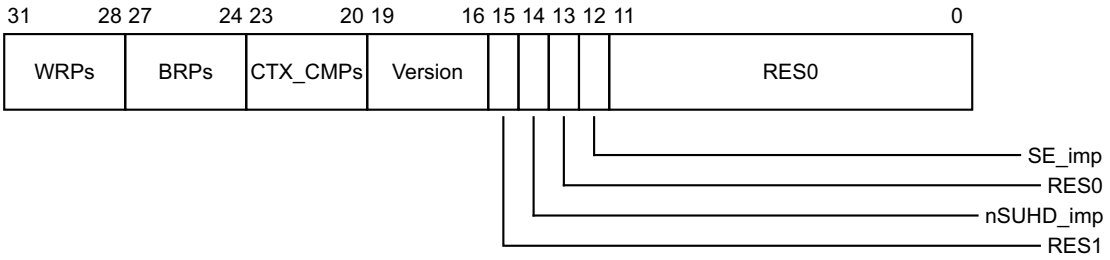
Attributes

DBGDIDR is a 32-bit register.

Field descriptions

The DBGDIDR bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



WRPs, bits [31:28]

The number of watchpoints implemented, minus 1.

Permitted values of this field are from `0b0001` for 2 implemented watchpoints, to `0b1111` for 16 implemented watchpoints.

The value of `0b0000` is reserved.

If AArch64 is implemented, this field has the same value as ID_AA64DFR0_EL1.WRPs.

BRPs, bits [27:24]

The number of breakpoints implemented, minus 1.

Permitted values of this field are from `0b0001` for 2 implemented breakpoint, to `0b1111` for 16 implemented breakpoints.

The value of `0b0000` is reserved.

If AArch64 is implemented, this field has the same value as ID_AA64DFR0_EL1.BRPs.

CTX_CMPs, bits [23:20]

The number of breakpoints that can be used for Context matching, minus 1.

Permitted values of this field are from `0b0000` for 1 Context matching breakpoint, to `0b1111` for 16 Context matching breakpoints.

The Context matching breakpoints must be the highest addressed breakpoints. For example, if six breakpoints are implemented and two are Context matching breakpoints, they must be breakpoints 4 and 5.

If AArch64 is implemented, this field has the same value as ID_AA64DFR0_EL1.CTX_CMPs.

Version, bits [19:16]

The Debug architecture version. Defined values are:

`0001` ARMv6, v6 Debug architecture

`0010` ARMv6, v6.1 Debug architecture

`0011` ARMv7, v7 Debug architecture, with baseline CP14 registers implemented

`0100` ARMv7, v7 Debug architecture, with all CP14 registers implemented

`0101` ARMv7, v7.1 Debug architecture.

`0110` ARMv8, v8 Debug architecture.

All other values are reserved.

Bit [15]

Reserved, RES1.

nSUHD_imp, bit [14]

In ARMv7-A, was Secure User Halting Debug not implemented.

The value of this bit must match the value of the SE_imp bit.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Bit [13]

Reserved, RES0.

SE_imp, bit [12]

EL3 implemented. The meanings of the values of this bit are:

0 EL3 not implemented.

1 EL3 implemented.

The value of this bit must match the value of the nSUHD_imp bit.

Bits [11:0]

Reserved, RES0.

Accessing the DBGDIDR:

To access the DBGDIDR:

```
MRC p14,0,<Rt>,c0,c0,0 ; Read DBGDIDR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0000	000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.12 DBGDRAR, Debug ROM Address Register

The DBGDRAR characteristics are:

Purpose

Defines the base physical address of a 4KB-aligned memory-mapped debug component, usually a ROM table that locates and describes the memory-mapped debug components in the system. ARMv8 deprecates any use of this register.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RO	RO	RO

ARMv8 deprecates any use of this register.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If DBGDSCRext.UDCCdis==1, read accesses to this register from PL0 are trapped to Undefined mode.

If HDCR.TDRA==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TDRA==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

If MDSCR_EL1.TDCC==1, read accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGDRAR is architecturally mapped to AArch64 System register MDRAR_EL1.

If EL1 cannot use AArch32 then the implementation of this register is OPTIONAL and deprecated.

Attributes

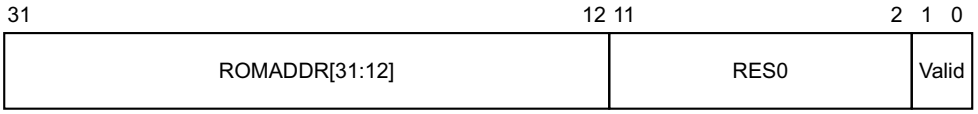
DBGDRAR is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, bits [31:0] are read.

Field descriptions

The DBGDRAR bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

When accessing as a 32-bit register:



ROMADDR[31:12], bits [31:12]

Bits[31:12] of the ROM table physical address. Bits [11:0] of the address are zero.

In an implementation that includes EL3, ROMADDR is an address in Non-secure memory. It is IMPLEMENTATION DEFINED whether the ROM table is also accessible in Secure memory.

Bits [11:2]

Reserved, RES0.

Valid, bits [1:0]

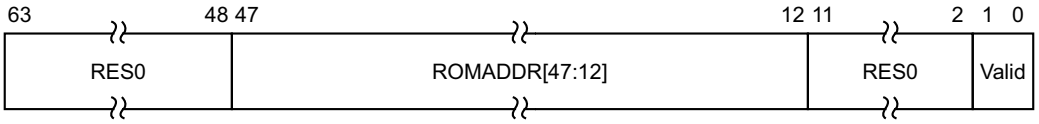
This field indicates whether the ROM Table address is valid. The permitted values of this field are:

`00` ROM Table address is not valid. Software must ignore ROMADDR.

`11` ROM Table address is valid.

Other values are reserved.

When accessing as a 64-bit register:



Bits [63:48]

Reserved, RES0.

ROMADDR[47:12], bits [47:12]

Bits[47:12] of the ROM table physical address.

If the physical address size in bits (PAsize) is less than 48 then the register bits corresponding to ROMADDR [47:PAsize] are RES0.

Bits [11:0] of the ROM table physical address are zero.

ARM strongly recommends that bits ROMADDR[(PAsize-1):32] are zero in any system that supports AArch32 at the highest implemented Exception level.

In an implementation that includes EL3, ROMADDR is an address in Non-secure memory. It is IMPLEMENTATION DEFINED whether the ROM table is also accessible in Secure memory.

Bits [11:2]

Reserved, RES0.

Valid, bits [1:0]

This field indicates whether the ROM Table address is valid. The permitted values of this field are:

`00` ROM Table address is not valid. Software must ignore ROMADDR.

`11` ROM Table address is valid.

Other values are reserved.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the DBGDRAR:

To access the DBGDRAR when accessing as a 32-bit register:

```
MRC p14,0,<Rt>,c1,c0,0 ; Read DBGDRAR[31:0] into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0001	0000	000

To access the DBGDRAR when accessing as a 64-bit register:

```
MRRC p14,0,<Rt>,<Rt2>,c1 ; Read DBGDRAR[31:0] into Rt and DBGDRAR[63:32] into Rt2
```

Register access is encoded as follows:

coproc	opc1	CRm
1110	0000	0001

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.13 DBGDSAR, Debug Self Address Register

The DBGDSAR characteristics are:

Purpose

In earlier versions of the ARM Architecture, this register defines the offset from the base address defined in DBGDRAR of the physical base address of the debug registers for the PE. ARMv8 deprecates any use of this register.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RO	RO	RO

ARMv8 deprecates any use of this register.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If DBGDSCRext.UDCCdis==1, read accesses to this register from PL0 are trapped to Undefined mode.

If HDCR.TDRA==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TDRA==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, read accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If MDSCR_EL1.TDCC==1, read accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

If EL1 cannot use AArch32 then the implementation of this register is OPTIONAL and deprecated.

Attributes

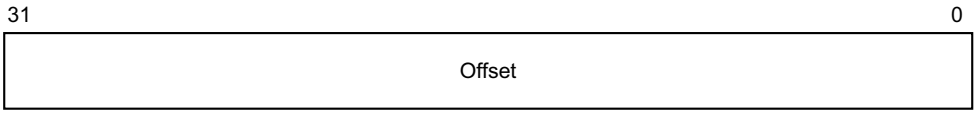
DBGDSAR is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, bits [31:0] are read.

Field descriptions

The DBGDSAR bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

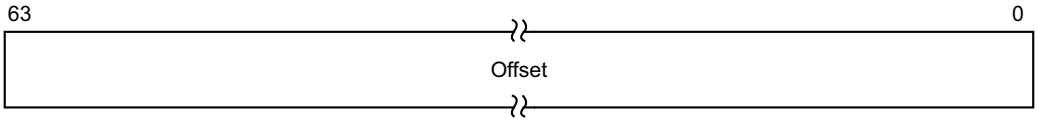
When accessing as a 32-bit register:



Offset, bits [31:0]

This register value is RAZ.

When accessing as a 64-bit register:



Offset, bits [63:0]

This register value is RAZ.

Accessing the DBGDSAR:

To access the DBGDSAR when accessing as a 32-bit register:

```
MRC p14,0,<Rt>,c2,c0,0 ; Read DBGDSAR[31:0] into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0010	0000	000

To access the DBGDSAR when accessing as a 64-bit register:

```
MRRC p14,0,<Rt>,<Rt2>,c2 ; Read DBGDSAR[31:0] into Rt and DBGDSAR[63:32] into Rt2
```

Register access is encoded as follows:

coproc	opc1	CRm
1110	0000	0010

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.14 DBGDSCRext, Debug Status and Control Register, External View

The DBGDSCRext characteristics are:

Purpose

Main control register for the debug implementation.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGDSCRext is architecturally mapped to AArch64 System register MDSCR_EL1.

This register is required in all implementations.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

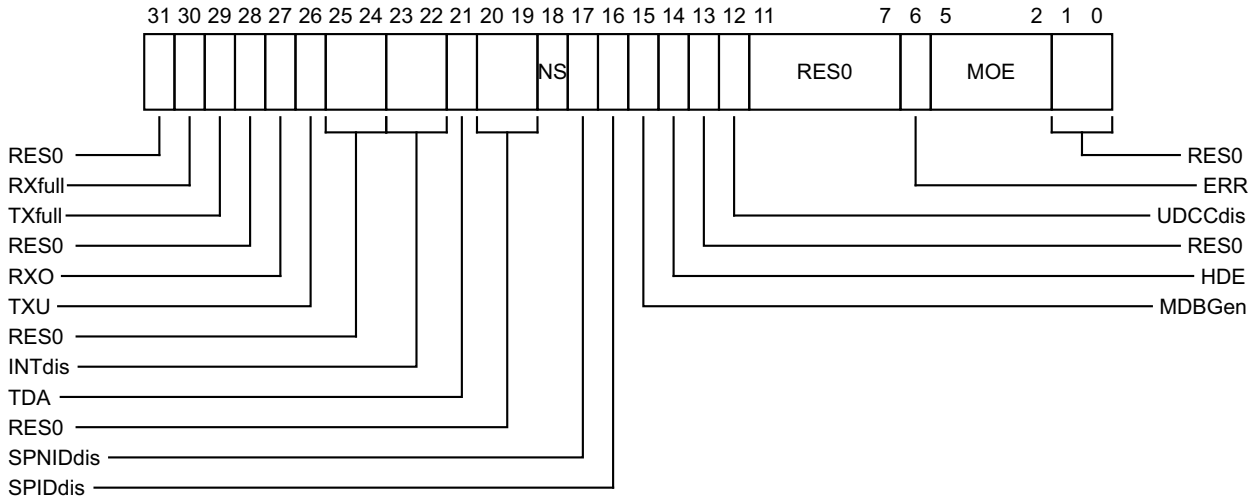
Attributes

DBGDSCRext is a 32-bit register.

Field descriptions

The DBGDSCRext bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



Bit [31]

Reserved, RES0.

RXfull, bit [30]

DTRRX full. Used for save/restore of EDSCR.RXfull.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.

ARM deprecates use of this bit other than for save/restore. Use DBGDSCRint to access the DTRRX full status.

The architected behavior of this field determines the value it returns after a reset.

TXfull, bit [29]

DTRTX full. Used for save/restore of EDSCR.TXfull.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.

ARM deprecates use of this bit other than for save/restore. Use DBGDSCRint to access the DTRTX full status.

The architected behavior of this field determines the value it returns after a reset.

Bit [28]

Reserved, RES0.

RXO, bit [27]

Used for save/restore of EDSCR.RXO.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.

The architected behavior of this field determines the value it returns after a reset.

TXU, bit [26]

Used for save/restore of EDSCR.TXU.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.

The architected behavior of this field determines the value it returns after a reset.

Bits [25:24]

Reserved, RES0.

INTdis, bits [23:22]

Used for save/restore of EDSCR.INTdis.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this field is RO, and software must treat it as UNK/SBZP.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this field is RW.

The architected behavior of this field determines the value it returns after a reset.

TDA, bit [21]

Used for save/restore of EDSCR.TDA.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.

The architected behavior of this field determines the value it returns after a reset.

Bits [20:19]

Reserved, RES0.

NS, bit [18]

Non-secure status. Returns the inverse of IsSecure(). This bit is RO.

ARM deprecates use of this field.

SPNIDdis, bit [17]

Secure privileged profiling disabled status bit. This bit is RO and reflects the value of ProfilingProhibited(TRUE,EL1). Permitted values are:

`0` Profiling allowed in Secure privileged modes.

`1` Profiling prohibited in Secure privileged modes.

ARM deprecates use of this field.

SPIDdis, bit [16]

Secure privileged AArch32 invasive self-hosted debug disabled status bit. This bit is RO and depends on the value of SDCR.SPD and the pseudocode function AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled(). Permitted values are:

`0` Self-hosted debug enabled in Secure privileged AArch32 modes.

`1` Self-hosted debug disabled in Secure privileged AArch32 modes.

This bit reads as 1 if any of the following is true and reads as 0 otherwise:

- SDCR.SPD has the value `10`.
- SDCR.SPD has the value `00` and AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled() returns FALSE.

ARM deprecates use of this field.

MDBGen, bit [15]

Monitor debug events enable. Enable Breakpoint, Watchpoint, and Vector catch debug exceptions.

`0` Breakpoint, Watchpoint, and Vector catch debug exceptions disabled.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

1 Breakpoint, Watchpoint, and Vector catch debug exceptions enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

HDE, bit [14]

Used for save/restore of EDSCR.HDE.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.

The architected behavior of this field determines the value it returns after a reset.

Bit [13]

Reserved, RES0.

UDCCdis, bit [12]

Traps PL0 accesses to the DCC registers to Undefined mode.

0 PL0 accesses to the DCC registers are not trapped to Undefined mode.

1 PL0 accesses to the DBGDSCRint, DBGDTRRXint, DBGDTRTXint, DBGDIDR, DBGDSAR, and DBGDRAR are trapped to Undefined mode.

Note

All accesses to these registers are trapped, including LDC and STC accesses to DBGDTRTXint and DBGDTRRXint, and MRRC accesses to DBGDSAR and DBGDRAR.

Traps of PL0 accesses to the DBGDTRRXint and DBGDTRTXint are ignored in Debug state.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [11:7]

Reserved, RES0.

ERR, bit [6]

Used for save/restore of EDSCR.ERR.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.

The architected behavior of this field determines the value it returns after a reset.

MOE, bits [5:2]

Method of Entry for debug exception. When a debug exception is taken to an Exception level using AArch32, this field is set to indicate the event that caused the exception:

0001 Breakpoint

0011 Software breakpoint (BKPT) instruction

0101 Vector catch

1010 Watchpoint

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bits [1:0]

Reserved, RES0.

Accessing the DBGDSCRext:

To access the DBGDSCRext:

Non-Confidential - Beta

G6.3.15 DBGDSCRint, Debug Status and Control Register, Internal View

The DBGDSCRint characteristics are:

Purpose

Main control register for the debug implementation. This is an internal, read-only view.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RO	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If DBGDSCRext.UDCCdis==1, read accesses to this register from PL0 are trapped to Undefined mode.

If HDCR.TDA==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, read accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If MDSCR_EL1.TDCC==1, read accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGDSCRint is architecturally mapped to AArch64 System register MDCCSR_EL0.

This register is required in all implementations.

DBGDSCRint.{NS, SPNIDdis, SPIDdis, MDBGen, UDCCdis, MOE} are UNKNOWN when the register is accessed at EL0. However, although these values are not accessible at EL0 by instructions that are neither UNPREDICTABLE nor return UNKNOWN values, it is permissible for an implementation to return the values of DBGDSCRext.{NS, SPNIDdis, SPIDdis, MDBGen, UDCCdis, MOE} for these fields at EL0.

It is also permissible for an implementation to return the same values as defined for a read of DBGDSCRint at EL1 or above. (This is the case even if the implementation does not support AArch32 at EL1 or above.)

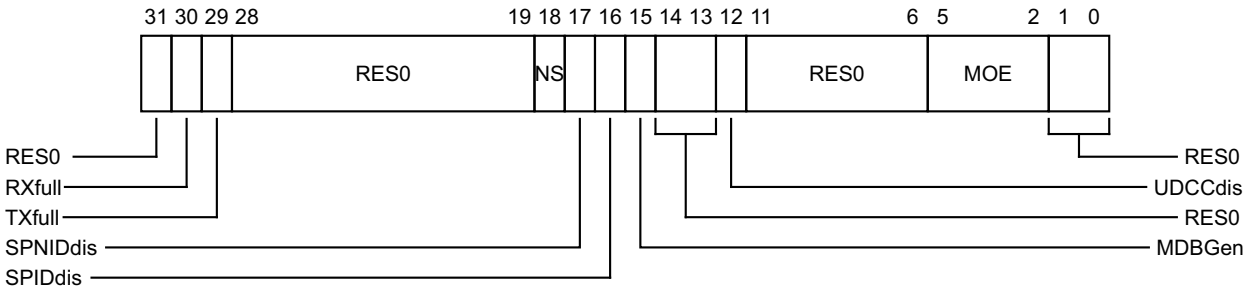
Attributes

DBGDSCRint is a 32-bit register.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Field descriptions

The DBGDSCRint bit assignments are:



Bit [31]

Reserved, RES0.

RXfull, bit [30]

DTRRX full. Read-only view of the equivalent bit in the EDSCR.

TXfull, bit [29]

DTRTX full. Read-only view of the equivalent bit in the EDSCR.

Bits [28:19]

Reserved, RES0.

NS, bit [18]

Non-secure status.

Read-only view of the equivalent bit in the DBGDSCRext. ARM deprecates use of this field.

SPNIDdis, bit [17]

Secure privileged non-invasive debug disable.

Read-only view of the equivalent bit in the DBGDSCRext. ARM deprecates use of this field.

SPIDdis, bit [16]

Secure privileged invasive debug disable.

Read-only view of the equivalent bit in the DBGDSCRext. ARM deprecates use of this field.

MDBGen, bit [15]

Monitor debug events enable.

Read-only view of the equivalent bit in the DBGDSCRext.

Bits [14:13]

Reserved, RES0.

UDCCdis, bit [12]

User mode access to Debug Communications Channel disable.

Read-only view of the equivalent bit in the DBGDSCRext. ARM deprecates use of this field.

Bits [11:6]

Reserved, RES0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

MOE, bits [5:2]

Method of Entry for debug exception. When a debug exception is taken to an Exception level using AArch32, this field is set to indicate the event that caused the exception:

`0001` Breakpoint

`0011` Software breakpoint (BKPT) instruction

`0101` Vector catch

`1010` Watchpoint

Read-only view of the equivalent bit in the DBGDSCRext.

Bits [1:0]

Reserved, RES0.

Accessing the DBGDSCRint:

To access the DBGDSCRint:

```
MRC p14,0,<Rt>,c0,c1,0 ; Read DBGDSCRint into Rt, where Rt can be R0-R14 or APSR_nzcv. The last form writes bits[31:28] of the transferred value to the N, Z, C and V condition flags and is specified by setting the RT field of the encoding to 0b1111.
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0001	000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.16 DBGDTRRXext, Debug OS Lock Data Transfer Register, Receive, External View

The DBGDTRRXext characteristics are:

Purpose

Used for save/restore of DBGDTRRXint. It is a component of the Debug Communications Channel.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

ARM deprecates reads and writes of DBGDTRRXext through the CP14 interface when the OS lock is unlocked.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

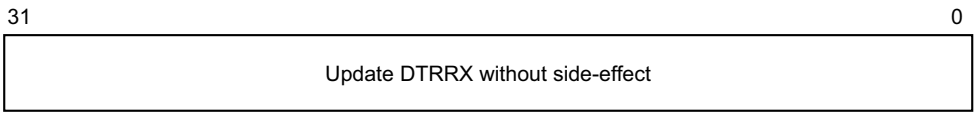
AArch32 System register DBGDTRRXext is architecturally mapped to AArch64 System register OSDTRRX_EL1.

Attributes

DBGDTRRXext is a 32-bit register.

Field descriptions

The DBGDTRRXext bit assignments are:



Bits [31:0]

Update DTRRX without side-effect.

Writes to this register update the value in DTRRX and do not change RXfull.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Reads of this register return the last value written to DTRRX and do not change RXfull.

For the full behavior of the Debug Communications Channel, see Chapter H4 *The Debug Communication Channel and Instruction Transfer Register*.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the DBGDTRRXext:

To access the DBGDTRRXext:

```
MRC p14,0,<Rt>,c0,c0,2 ; Read DBGDTRRXext into Rt
MCR p14,0,<Rt>,c0,c0,2 ; Write Rt to DBGDTRRXext
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0000	010

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.17 DBGDTRRXint, Debug Data Transfer Register, Receive

The DBGDTRRXint characteristics are:

Purpose

Transfers data from an external debugger to the PE. For example, it is used by a debugger transferring commands and data to a debug target. It is a component of the Debug Communications Channel.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RO	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If DBGDSCRext.UDCCdis==1, read accesses to this register from PL0 are trapped to Undefined mode.

If HDCR.TDA==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, read accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If MDSCR_EL1.TDCC==1, read accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGDTRRXint is architecturally mapped to AArch64 System register DBGDTRRX_EL0.

AArch32 System register DBGDTRRXint is architecturally mapped to External register DBGDTRRX_EL0.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

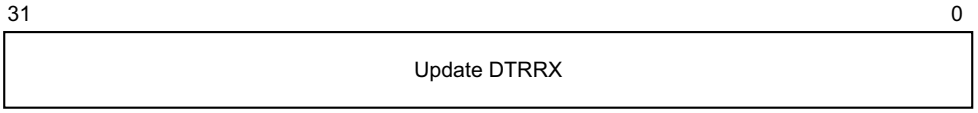
Attributes

DBGDTRRXint is a 32-bit register.

Field descriptions

The DBGDTRRXint bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



Bits [31:0]

Update DTRRX.

If RXfull is set to 1, then reads of this register return the last value written to DTRRX and clear RXfull to 0.

For the full behavior of the Debug Communications Channel, see Chapter H4 *The Debug Communication Channel and Instruction Transfer Register*.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the DBGDTRRXint:

To access the DBGDTRRXint:

```
MRC p14,0,<Rt>,c0,c5,0 ; Read DBGDTRRXint into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0101	000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.18 DBGDTRTXext, Debug OS Lock Data Transfer Register, Transmit

The DBGDTRTXext characteristics are:

Purpose

Used for save/restore of DBGDTRTXint. It is a component of the Debug Communication Channel.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

ARM deprecates reads and writes of DBGDTRTXext through the CP14 interface when the OS lock is unlocked.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

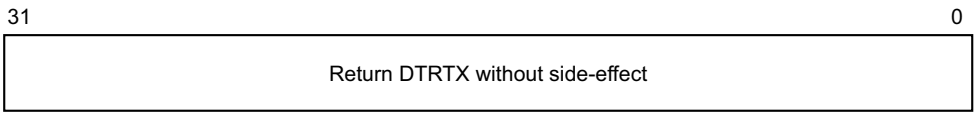
AArch32 System register DBGDTRTXext is architecturally mapped to AArch64 System register OSDTRTX_EL1.

Attributes

DBGDTRTXext is a 32-bit register.

Field descriptions

The DBGDTRTXext bit assignments are:



Bits [31:0]

Return DTRTX without side-effect.

Reads of this register return the value in DTRTX and do not change TXfull.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Writes of this register update the value in DTRTX and do not change TXfull.

For the full behavior of the Debug Communications Channel, see Chapter H4 *The Debug Communication Channel and Instruction Transfer Register*.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the DBGDTRTXext:

To access the DBGDTRTXext:

```
MRC p14,0,<Rt>,c0,c3,2 ; Read DBGDTRTXext into Rt
MCR p14,0,<Rt>,c0,c3,2 ; Write Rt to DBGDTRTXext
```

Register access is encoded as follows:

1110	000	0000	0011	010

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.19 DBGDTRTXint, Debug Data Transfer Register, Transmit

The DBGDTRTXint characteristics are:

Purpose

Transfers data from the PE to an external debugger. For example, it is used by a debug target to transfer data to the debugger. It is a component of the Debug Communication Channel.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-WO	Config-WO	WO	WO	WO	WO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-WO	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If DBGDSCRext.UDCCdis==1, write accesses to this register from PL0 are trapped to Undefined mode.

If HDCR.TDA==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, write accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If MDSCR_EL1.TDCC==1, write accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGDTRTXint is architecturally mapped to AArch64 System register DBGDTRTX_EL0.

AArch32 System register DBGDTRTXint is architecturally mapped to External register DBGDTRTX_EL0.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

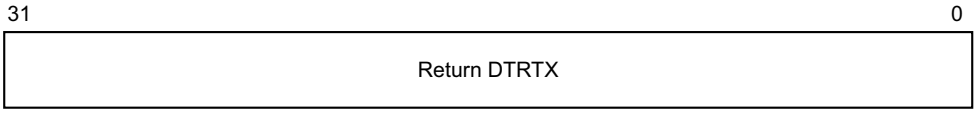
Attributes

DBGDTRTXint is a 32-bit register.

Field descriptions

The DBGDTRTXint bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



Bits [31:0]

Return DTRTX.

If TXfull is set to 0, then writes of this register update the value in DTRTX and set TXfull to 1.

For the full behavior of the Debug Communications Channel, see Chapter H4 *The Debug Communication Channel and Instruction Transfer Register*.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the DBGDTRTXint:

To access the DBGDTRTXint:

```
MCR p14,0,<Rt>,c0,c5,0 ; Write Rt to DBGDTRTXint
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0101	000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.20 DBGOSDLR, Debug OS Double Lock Register

The DBGOSDLR characteristics are:

Purpose

Locks out the external debug interface.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TDOSA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDOSA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDOSA==1, accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGOSDLR is architecturally mapped to AArch64 System register OSDLR_EL1.

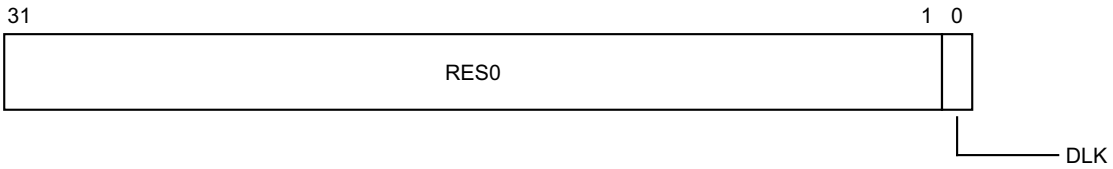
This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DBGOSDLR is a 32-bit register.

Field descriptions

The DBGOSDLR bit assignments are:



Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Bits [31:1]

Reserved, RES0.

DLK, bit [0]

OS Double Lock control bit. Possible values are:

`0` OS Double Lock unlocked.

`1` OS Double Lock locked, if DBGPRCR.CORENPDRQ (Core no powerdown request) bit is set to 0 and the PE is in Non-debug state.

When this register has an architecturally-defined reset value, this field resets to `0`.

Accessing the DBGOSDLR:

To access the DBGOSDLR:

```
MRC p14,0,<Rt>,c1,c3,4 ; Read DBGOSDLR into Rt
MCR p14,0,<Rt>,c1,c3,4 ; Write Rt to DBGOSDLR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0001	0011	100

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.21 DBGOSECCR, Debug OS Lock Exception Catch Control Register

The DBGOSECCR characteristics are:

Purpose

Provides a mechanism for an operating system to access the contents of EDECCR that are otherwise invisible to software, so it can save/restore the contents of EDECCR over powerdown on behalf of the external debugger.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGOSECCR is architecturally mapped to AArch64 System register OSECCR_EL1.

AArch32 System register DBGOSECCR is architecturally mapped to External register EDECCR.

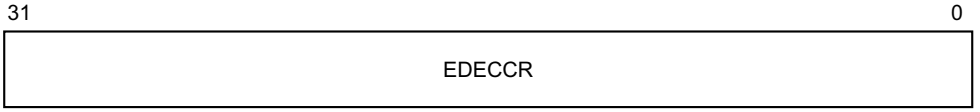
Attributes

DBGOSECCR is a 32-bit register.

Field descriptions

The DBGOSECCR bit assignments are:

When OSLSR.OSLK==1:



Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

EDECCR, bits [31:0]

Used for save/restore to EDECCR over powerdown.

Accessing the DBGOSECCR:

To access the DBGOSECCR:

```
MRC p14,0,<Rt>,c0,c6,2 ; Read DBGOSECCR into Rt
MCR p14,0,<Rt>,c0,c6,2 ; Write Rt to DBGOSECCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2

G6.3.22 DBGOSLAR, Debug OS Lock Access Register

The DBGOSLAR characteristics are:

Purpose

Provides a lock for the debug registers. The OS lock also disables some Software debug events.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TDOSA==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDOSA==1, Non-secure write accesses to this register from EL1 are trapped to EL2 using AArch64.

If MDCR_EL3.TDOSA==1, write accesses to this register from PL1 and PL2 are trapped to EL3 using AArch64.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGOSLAR is architecturally mapped to AArch64 System register OSLAR_EL1.

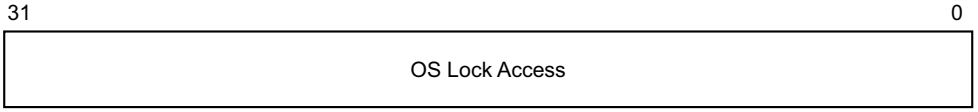
AArch32 System register DBGOSLAR is architecturally mapped to External register OSLAR_EL1.

Attributes

DBGOSLAR is a 32-bit register.

Field descriptions

The DBGOSLAR bit assignments are:



Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Bits [31:0]

OS Lock Access. Writing the value `0xC5ACCE55` to the DBGOSLAR sets the OS lock to 1. Writing any other value sets the OS lock to 0.

Use DBGOSLSR.OSLK to check the current status of the lock.

Accessing the DBGOSLAR:

To access the DBGOSLAR:

```
MCR p14,0,<Rt>,c1,c0,4 ; Write Rt to DBGOSLAR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0001	0000	100

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.23 DBGOSLSR, Debug OS Lock Status Register

The DBGOSLSR characteristics are:

Purpose

Provides status information for the OS lock.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TDOSA==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDOSA==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDOSA==1, read accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGOSLSR is architecturally mapped to AArch64 System register OSLSR_EL1.

The OS lock status is also visible in the external debug interface through EDPRSR.

This register is in the Cold reset domain. Some or all RW fields of this register have defined reset values. On a Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

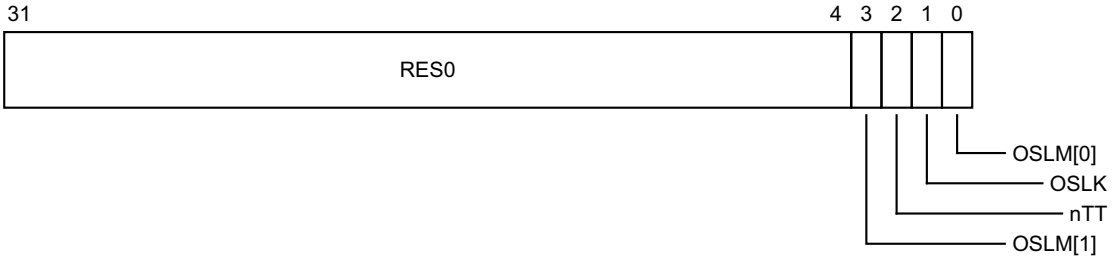
Attributes

DBGOSLSR is a 32-bit register.

Field descriptions

The DBGOSLSR bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



Bits [31:4]

Reserved, RES0.

OSLM[1], bit [3]

See below for description of the OSLM field.

nTT, bit [2]

Not 32-bit access. This bit is always RAZ. It indicates that a 32-bit access is needed to write the key to the OS Lock Access Register.

OSLK, bit [1]

OS Lock Status. The possible values are:

`0` OS lock unlocked.

`1` OS lock locked.

The OS lock is locked and unlocked by writing to the OS Lock Access Register.

When this register has an architecturally-defined reset value, this field resets to `1`.

OSLM[0], bit [0]

OS lock model implemented. Identifies the form of OS save and restore mechanism implemented. In ARMv8 these bits are as follows:

`10` OS lock implemented. DBGOSSRR not implemented.

All other values are reserved.

Accessing the DBGOSLSR:

To access the DBGOSLSR:

```
MRC p14,0,<Rt>,c1,c1,4 ; Read DBGOSLSR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0001	0001	100

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.24 DBGPRCR, Debug Power Control Register

The DBGPRCR characteristics are:

Purpose

Controls behavior of the PE on powerdown request.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TDOSA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDOSA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDOSA==1, accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGPRCR is architecturally mapped to AArch64 System register DBGPRCR_EL1.

Bit [0] of this register is mapped to EDPRCR.CORENPDRQ, bit [0] of the external view of this register.

The other bits in these registers are not mapped to each other.

This register is in the Cold reset domain. Some or all RW fields of this register have defined reset values. On a Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

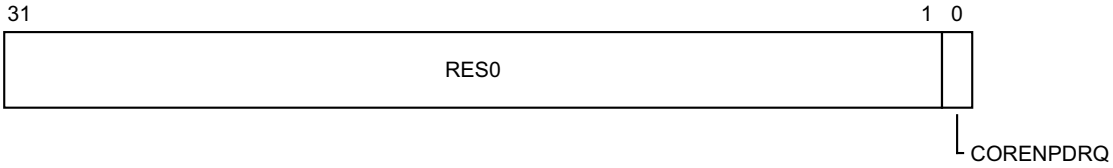
Attributes

DBGPRCR is a 32-bit register.

Field descriptions

The DBGPRCR bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



Bits [31:1]

Reserved, RES0.

CORENPDRQ, bit [0]

Core no powerdown request. Requests emulation of powerdown. Possible values of this bit are:

0 If the system responds to a powerdown request, it powers down Core power domain.

1 If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

Writes to this bit are permitted regardless of the state of the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request Core no powerdown regardless of whether invasive debug is permitted.

It is IMPLEMENTATION DEFINED whether this bit is reset to the value of EDPRCR.COREPURQ on exit from an IMPLEMENTATION DEFINED software-visible retention state.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, this field resets to the value of EDPRCR.COREPURQ, which is itself set to 0 on External Debug reset. If an External Debug reset and a Cold reset are coincident, DBGPRCR.CORENPDRQ is reset to 0.

Accessing the DBGPRCR:

To access the DBGPRCR:

```
MRC p14,0,<Rt>,c1,c4,4 ; Read DBGPRCR into Rt
MCR p14,0,<Rt>,c1,c4,4 ; Write Rt to DBGPRCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0001	0100	100

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.25 DBGVCR, Debug Vector Catch Register

The DBGVCR characteristics are:

Purpose

Controls Vector catch debug events.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGVCR is architecturally mapped to AArch64 System register DBGVCR32_EL2.

This register is required in all implementations.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

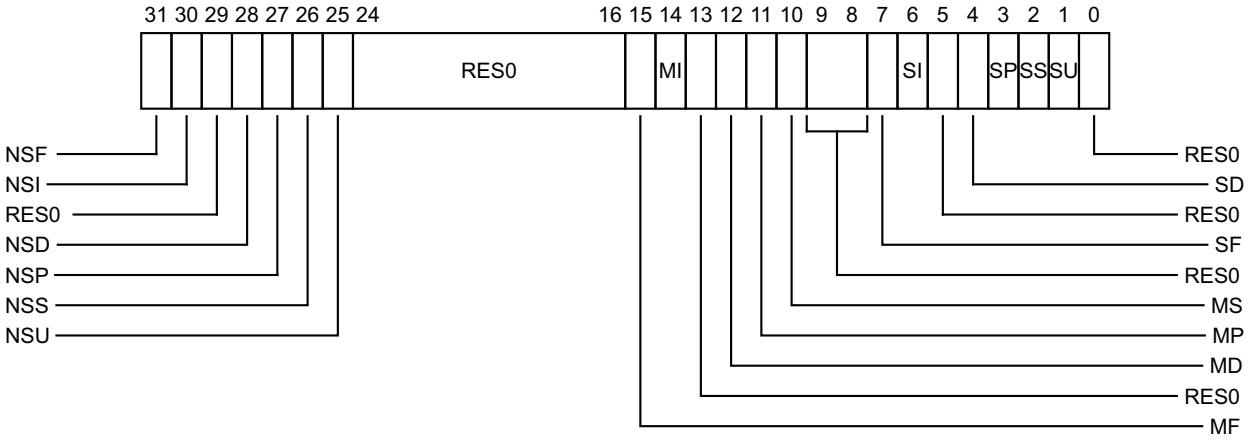
DBGVCR is a 32-bit register.

Field descriptions

The DBGVCR bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

When EL3 implemented and using AArch32:



NSF, bit [31]

FIQ vector catch enable in Non-secure state.

The exception vector offset is `0x1C`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

NSI, bit [30]

IRQ vector catch enable in Non-secure state.

The exception vector offset is `0x18`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bit [29]

Reserved, RES0.

NSD, bit [28]

Data Abort vector catch enable in Non-secure state.

The exception vector offset is `0x10`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

NSP, bit [27]

Prefetch Abort vector catch enable in Non-secure state.

The exception vector offset is `0x0C`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

NSS, bit [26]

Supervisor Call (SVC) vector catch enable in Non-secure state.

The exception vector offset is `0x08`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

NSU, bit [25]

Undefined Instruction vector catch enable in Non-secure state.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

The exception vector offset is 0x04.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bits [24:16]

Reserved, RES0.

MF, bit [15]

FIQ vector catch enable in Monitor mode.

The exception vector offset is 0x1C.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

MI, bit [14]

IRQ vector catch enable in Monitor mode.

The exception vector offset is 0x18.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bit [13]

Reserved, RES0.

MD, bit [12]

Data Abort vector catch enable in Monitor mode.

The exception vector offset is 0x10.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

MP, bit [11]

Prefetch Abort vector catch enable in Monitor mode.

The exception vector offset is 0x0C.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

MS, bit [10]

Secure Monitor Call (SMC) vector catch enable in Monitor mode.

The exception vector offset is 0x08.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bits [9:8]

Reserved, RES0.

SF, bit [7]

FIQ vector catch enable in Secure state.

The exception vector offset is 0x1C.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

SI, bit [6]

IRQ vector catch enable in Secure state.

The exception vector offset is 0x18.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bit [5]

Reserved, RES0.

SD, bit [4]

Data Abort vector catch enable in Secure state.

The exception vector offset is `0x10`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

SP, bit [3]

Prefetch Abort vector catch enable in Secure state.

The exception vector offset is `0x0C`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

SS, bit [2]

Supervisor Call (SVC) vector catch enable in Secure state.

The exception vector offset is `0x08`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

SU, bit [1]

Undefined Instruction vector catch enable in Secure state.

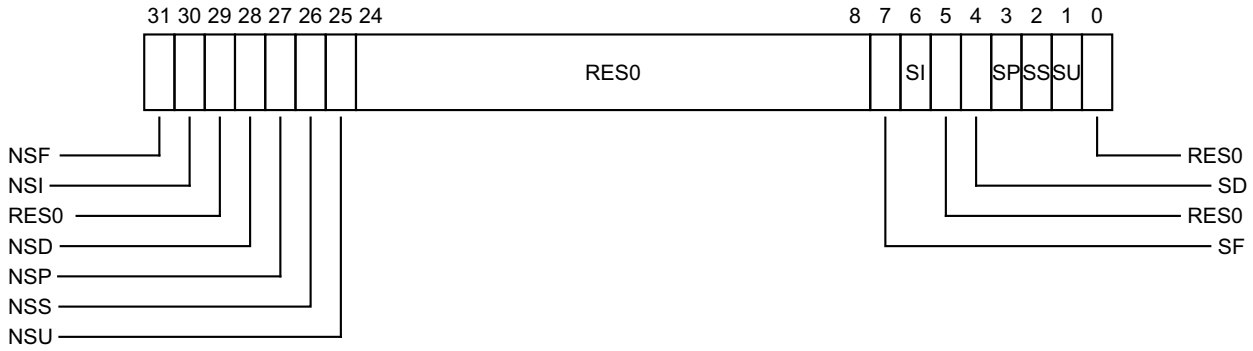
The exception vector offset is `0x04`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bit [0]

Reserved, RES0.

When EL3 implemented and using AArch64:



NSF, bit [31]

FIQ vector catch enable in Non-secure state.

The exception vector offset is `0x1C`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

NSI, bit [30]

IRQ vector catch enable in Non-secure state.

The exception vector offset is `0x18`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bit [29]

Reserved, RES0.

NSD, bit [28]

Data Abort vector catch enable in Non-secure state.

The exception vector offset is `0x10`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

NSP, bit [27]

Prefetch Abort vector catch enable in Non-secure state.

The exception vector offset is `0x0C`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

NSS, bit [26]

Supervisor Call (SVC) vector catch enable in Non-secure state.

The exception vector offset is `0x08`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

NSU, bit [25]

Undefined Instruction vector catch enable in Non-secure state.

The exception vector offset is `0x04`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bits [24:8]

Reserved, RES0.

SF, bit [7]

FIQ vector catch enable in Secure state.

The exception vector offset is `0x1C`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

SI, bit [6]

IRQ vector catch enable in Secure state.

The exception vector offset is `0x18`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bit [5]

Reserved, RES0.

SD, bit [4]

Data Abort vector catch enable in Secure state.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

The exception vector offset is 0x10.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

SP, bit [3]

Prefetch Abort vector catch enable in Secure state.

The exception vector offset is 0x0C.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

SS, bit [2]

Supervisor Call (SVC) vector catch enable in Secure state.

The exception vector offset is 0x08.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

SU, bit [1]

Undefined Instruction vector catch enable in Secure state.

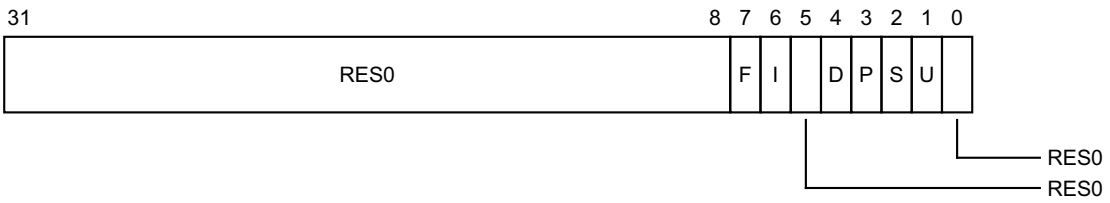
The exception vector offset is 0x04.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bit [0]

Reserved, RES0.

When EL3 not implemented:



Bits [31:8]

Reserved, RES0.

F, bit [7]

FIQ vector catch enable.

The exception vector offset is 0x1C.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

I, bit [6]

IRQ vector catch enable.

The exception vector offset is 0x18.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bit [5]

Reserved, RES0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

D, bit [4]

Data Abort vector catch enable.

The exception vector offset is `0x10`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

P, bit [3]

Prefetch Abort vector catch enable.

The exception vector offset `0x0C`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

S, bit [2]

Supervisor Call (SVC) vector catch enable.

The exception vector offset is `0x08`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

U, bit [1]

Undefined Instruction vector catch enable.

The exception vector offset is `0x04`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bit [0]

Reserved, RES0.

Accessing the DBGVCR:

To access the DBGVCR:

```
MRC p14,0,<Rt>,c0,c7,0 ; Read DBGVCR into Rt
MCR p14,0,<Rt>,c0,c7,0 ; Write Rt to DBGVCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0111	000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.26 DBGWCR<n>, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<n> characteristics are:

Purpose

Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<n>.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

When the E field is zero, all the other fields in the register are ignored.

Traps and Enables

For a description of the prioritization of any generated exceptions, see:

- *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state.
- *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.
- *Software Access debug event* on page H3-4753 for accesses to this register taken to Debug state.

Subject to the prioritization rules:

If EDSCR.TDA==1, DBGOSLSR.OSLK==0, and halting is allowed, EL1, EL2, and EL3 accesses to this register generate a Software Access debug event.

If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGWCR<n> is architecturally mapped to AArch64 System register DBGWCR<n>_EL1.

AArch32 System register DBGWCR<n> is architecturally mapped to External register DBGWCR<n>_EL1.

If breakpoint n is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

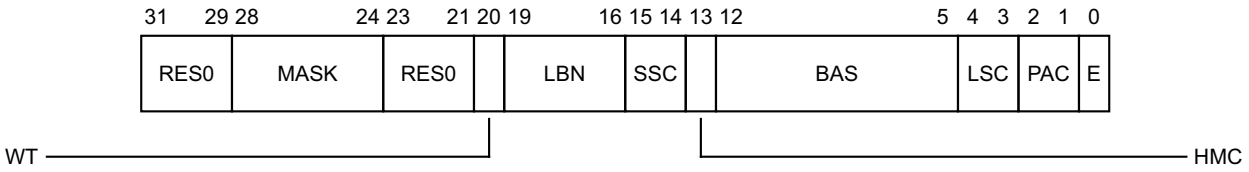
Attributes

DBGWCR<n> is a 32-bit register.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Field descriptions

The DBGWCR<n> bit assignments are:



Bits [31:29]

Reserved, RES0.

MASK, bits [28:24]

Address mask. Only objects up to 2GB can be watched using a single mask.

`00000` No mask.

`00001` Reserved.

`00010` Reserved.

If programmed with a reserved value, a watchpoint must behave as if either:

- MASK has been programmed with a defined value, which might be 0 (no mask), other than for a direct read of DBGWCRn_EL1.
- The watchpoint is disabled.

Software must not rely on this property because the behavior of reserved values might change in a future revision of the architecture.

Other values mask the corresponding number of address bits, from `0b00011` masking 3 address bits (`0x00000007` mask for address) to `0b11111` masking 31 address bits (`0x7FFFFFFF` mask for address).

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bits [23:21]

Reserved, RES0.

WT, bit [20]

Watchpoint type. Possible values are:

`0` Unlinked data address match.

`1` Linked data address match.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

LBN, bits [19:16]

Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

SSC, bits [15:14]

Security state control. Determines the Security states under which a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by DBGWVR<n> is being watched.

BAS	Description
xxxxxxx1	Match byte at DBGWVR<n>
xxxxxx1x	Match byte at DBGWVR<n>+1
xxxxx1xx	Match byte at DBGWVR<n>+2
xxxx1xxx	Match byte at DBGWVR<n>+3

In cases where DBGWVR<n> addresses a double-word:

BAS	Description, if DBGWVR<n>[2] == 0
xxx1xxxx	Match byte at DBGWVR<n>+4
xx1xxxxx	Match byte at DBGWVR<n>+5
x1xxxxxx	Match byte at DBGWVR<n>+6
1xxxxxxx	Match byte at DBGWVR<n>+7

If DBGWVR<n>[2] == 1, only BAS[3:0] are used and BAS[7:4] are ignored. ARM deprecates setting DBGWVR<n>[2] == 1.

The valid values for BAS are `0b0000000`, or a binary number all of whose set bits are contiguous. All other values are reserved and must not be used by software.

If BAS is zero, no bytes are watched by this watchpoint.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

`01` Match instructions that load from a watchpointed address.

`10` Match instructions that store to a watchpointed address.

`11` Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

PAC, bits [2:1]

Privilege of access control. Determines the Exception level or levels at which a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

E, bit [0]

Enable watchpoint n. Possible values are:

`0` Watchpoint disabled.

`1` Watchpoint enabled.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the DBGWCR<n>:

To access the DBGWCR<n>:

```
MRC p14,0,<Rt>,c0,<CRm>,7 ; Read DBGWCR<n> into Rt, where n is in the range 0 to 15
MCR p14,0,<Rt>,c0,<CRm>,7 ; Write Rt to DBGWCR<n>, where n is in the range 0 to 15
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	n<3:0>	111

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.27 DBGWFAR, Debug Watchpoint Fault Address Register

The DBGWFAR characteristics are:

Purpose

Previously returned information about the address of the instruction that accessed a watchpointed address. Is now deprecated and RES0.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

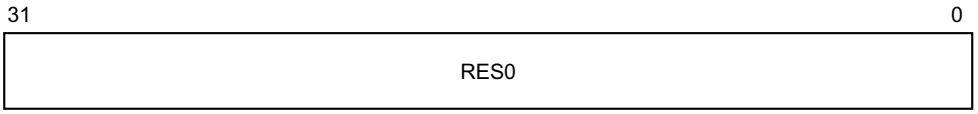
There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

DBGWFAR is a 32-bit register.

Field descriptions

The DBGWFAR bit assignments are:



Bits [31:0]

Reserved, RES0.

Accessing the DBGWFAR:

To access the DBGWFAR:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

```
MRC p14,0,<Rt>,c0,c6,0 ; Read DBGWFAR into Rt
MCR p14,0,<Rt>,c0,c6,0 ; Write Rt to DBGWFAR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0110	000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.28 DBGWVR<n>, Debug Watchpoint Value Registers, n = 0 - 15

The DBGWVR<n> characteristics are:

Purpose

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register DBGWCR<n>.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see:

- *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state.
- *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.
- *Software Access debug event* on page H3-4753 for accesses to this register taken to Debug state.

Subject to the prioritization rules:

If EDSCR.TDA==1, DBGOSLSR.OSLK==0, and halting is allowed, EL1, EL2, and EL3 accesses to this register generate a Software Access debug event.

If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, accesses to this register from PL1 and PL2 are trapped to EL3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGWVR<n> is architecturally mapped to AArch64 System register DBGWVR<n>_EL1[31:0].

AArch32 System register DBGWVR<n> is architecturally mapped to External register DBGWVR<n>_EL1[31:0].

If breakpoint n is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

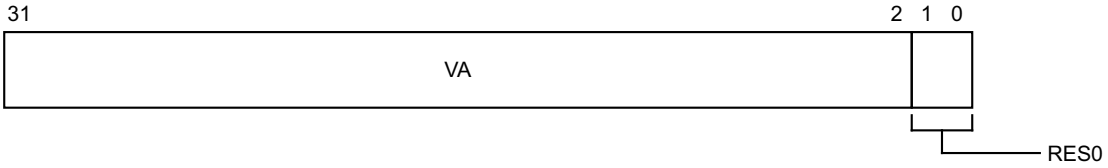
Attributes

DBGWVR<n> is a 32-bit register.

Field descriptions

The DBGWVR<n> bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



VA, bits [31:2]

Bits[31:2] of the address value for comparison.

ARM deprecates setting DBGWVR<n>[2] == 1.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bits [1:0]

Reserved, RES0.

Accessing the DBGWVR<n>:

To access the DBGWVR<n>:

```
MRC p14,0,<Rt>,c0,<CRm>,6 ; Read DBGWVR<n> into Rt, where n is in the range 0 to 15
MCR p14,0,<Rt>,c0,<CRm>,6 ; Write Rt to DBGWVR<n>, where n is in the range 0 to 15
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	n<3:0>	110

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.29 DLR, Debug Link Register

The DLR characteristics are:

Purpose

In Debug state, holds the address to restart from.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	RW	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
RW	RW	RW

Access to this register is from Debug state only. During normal execution this register is unallocated.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

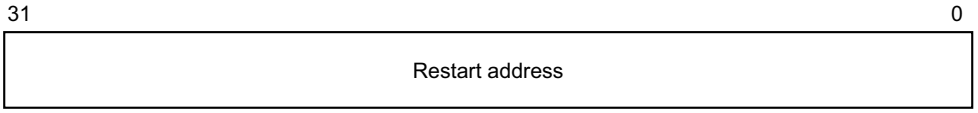
AArch32 System register DLR is architecturally mapped to AArch64 System register DLR_EL0[31:0].

Attributes

DLR is a 32-bit register.

Field descriptions

The DLR bit assignments are:



Bits [31:0]

Restart address.

Accessing the DLR:

To access the DLR:

```
MRC p15,3,<Rt>,c4,c5,1 ; Read DLR into Rt
MCR p15,3,<Rt>,c4,c5,1 ; Write Rt to DLR
```

Non-Confidential - Beta

G6.3.30 DSPSR, Debug Saved Program Status Register

The DSPSR characteristics are:

Purpose

Holds the saved process state on entry to Debug state.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	RW	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
RW	RW	RW

Access to this register is from Debug state only. During normal execution this register is unallocated.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DSPSR is architecturally mapped to AArch64 System register DSPSR_EL0.

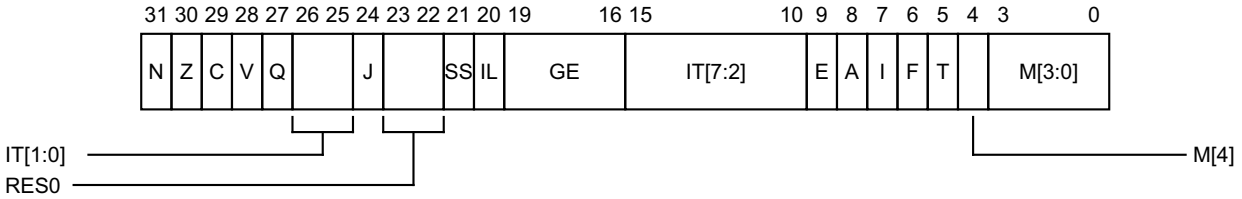
Attributes

DSPSR is a 32-bit register.

Field descriptions

The DSPSR bit assignments are:

When entering Debug state from AArch32 and exiting Debug state to AArch32:



N, bit [31]

Set to the value of CPSR.N on entering Debug state, and copied to CPSR.N on exiting Debug state.

Z, bit [30]

Set to the value of CPSR.Z on entering Debug state, and copied to CPSR.Z on exiting Debug state.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

C, bit [29]

Set to the value of CPSR.C on entering Debug state, and copied to CPSR.C on exiting Debug state.

V, bit [28]

Set to the value of CPSR.V on entering Debug state, and copied to CPSR.V on exiting Debug state.

Q, bit [27]

Set to the value of CPSR.Q on entering Debug state, and copied to CPSR.Q on exiting Debug state.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:22]

Reserved, RES0.

SS, bit [21]

Software step. Shows the value of PSTATE.SS immediately before Debug state was entered.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before Debug state was entered.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the Debug state entry was taken from. Possible values of this bit are:

`0` Taken from A32 state.

`1` Taken from T32 state.

M[4], bit [4]

Execution state that Debug state was entered from. Possible values of this bit are:

`1` Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that Debug state was entered from. The possible values are:

M[3:0]	Mode
`0b0000`	User
`0b0001`	FIQ
`0b0010`	IRQ
`0b0011`	Supervisor
`0b0110`	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
`0b0111`	Abort
`0b1010`	Hyp
`0b1011`	Undefined
`0b1111`	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5366.

Accessing the DSPSR:

To access the DSPSR:

```
MRC p15,3,<Rt>,c4,c5,0 ; Read DSPSR into Rt
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

```
MCR p15,3,<Rt>,c4,c5,0 ; Write Rt to DSPSR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.31 HDCR, Hyp Debug Control Register

The HDCR characteristics are:

Purpose

Controls the trapping to Hyp mode of Non-secure accesses, at EL1 or lower, to functions provided by the debug and trace architectures and the Performance Monitors Extension.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	-

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TDA==1, accesses to this register from PL2 are trapped to EL3 using AArch64.

Configurations

AArch32 System register HDCR is architecturally mapped to AArch64 System register MDCR_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

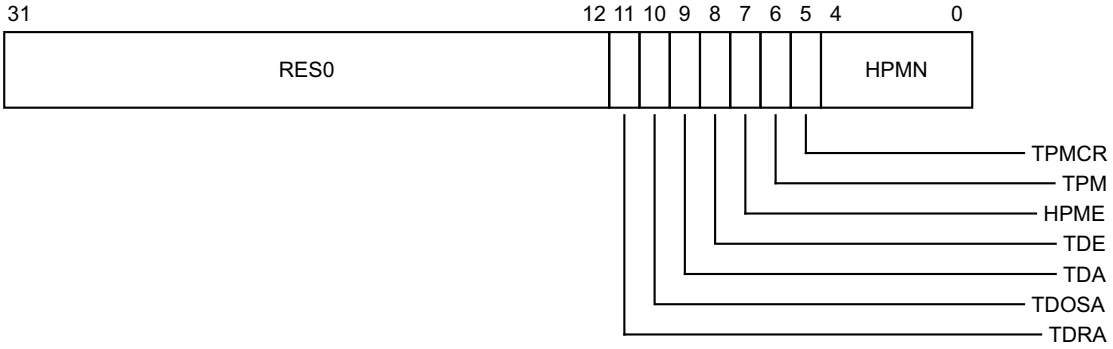
Attributes

HDCR is a 32-bit register.

Field descriptions

The HDCR bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



Bits [31:12]

Reserved, RES0.

TDRA, bit [11]

Trap Debug ROM Address register access. Traps Non-secure EL0 and EL1 CP14 accesses to the Debug ROM registers to Hyp mode.

`0` Non-secure EL0 and EL1 CP14 accesses to the Debug ROM registers are not trapped to Hyp mode.

`1` Non-secure EL0 and EL1 CP14 accesses to the DBGDRAR or DBGDSAR are trapped to Hyp mode.

If HCR.TGE or HDCR.TDE is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

When this register has an architecturally-defined reset value, this field resets to `0`.

TDOSA, bit [10]

Trap debug OS-related register access. Traps Non-secure EL1 CP14 accesses to the powerdown debug registers to Hyp mode.

`0` Non-secure EL1 CP14 accesses to the powerdown debug registers are not trapped to Hyp mode.

`1` Non-secure EL1 CP14 accesses to the powerdown debug registers are trapped to Hyp mode.

The registers for which accesses are trapped are as follows:

- DBGOSLSR, DBGOSLAR, DBGOSDLR, and the DBGPRCR.
- Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

Note

These registers are not accessible at PL0.

If HCR.TGE or HDCR.TDE is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

When this register has an architecturally-defined reset value, this field resets to `0`.

TDA, bit [9]

Trap debug access. Traps Non-secure EL0 and EL1 CP14 accesses to those CP14 registers that are not trapped by either of the following:

- HDCR.TDRA.
- HDCR.TDOSA.

`0` Has no effect on CP14 accesses to the debug registers.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

1 Non-secure EL0 or EL1 CP14 accesses to the debug registers, other than the registers trapped by HDCR.TDRA and HDCR.TDOSA, are trapped to Hyp mode.

HDCR.TDA does not trap accesses to the DBGDTRRXint or DBGDTRTXint when the PE is in Debug state.

If HCR.TGE or HDCR.TDE is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

When this register has an architecturally-defined reset value, this field resets to 0.

TDE, bit [8]

Trap Debug exceptions. The possible values of this bit are:

0 This control has no effect on the routing of debug exceptions, and has no effect on Non-secure accesses to debug registers.

1 In Non-secure state:

- Debug exceptions generated at EL1 or EL0 are routed to EL2.
- All accesses to Debug registers that would not be UNDEFINED if the value of this field was 0 are trapped to EL2.

When HCR_EL2.TGE == 1, the PE behaves as if the value of this field is 1 for all purposes other than returning the value of a direct read of the register.

When this register has an architecturally-defined reset value, this field resets to 0.

HPME, bit [7]

Hypervisor Performance Monitors Enable. The possible values of this bit are:

0 Hyp mode Performance Monitors disabled.

1 Hyp mode Performance Monitors enabled.

When the value of this bit is 1, the Performance Monitors counters that are reserved for use from Hyp mode or Secure state are enabled. For more information see the description of the HPMN field.

If the Performance Monitors Extension is not implemented, this field is RES0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

TPM, bit [6]

Trap Performance Monitors accesses. Traps Non-secure EL0 and EL1 accesses to all Performance Monitors registers to Hyp mode.

0 Non-secure EL0 and EL1 accesses to all Performance Monitors registers are not trapped to Hyp mode.

1 Non-secure EL0 and EL1 accesses to all Performance Monitors registers are trapped to Hyp mode.

Note

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

If the Performance Monitors Extension is not implemented, this field is RES0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

TPMCR, bit [5]

Trap PMCR accesses. Traps Non-secure EL0 and EL1 accesses to the PMCR to Hyp mode.

0 Non-secure EL0 and EL1 accesses to the PMCR are not trapped to Hyp mode.

1 Non-secure EL0 and EL1 accesses to the PMCR are trapped to Hyp mode.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Note

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

If the Performance Monitors Extension is not implemented, this field is RES0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to `0`.

HPMN, bits [4:0]

Defines the number of Performance Monitors counters that are accessible from Non-secure EL1 modes, and from Non-secure EL0 modes if unprivileged access is enabled.

If the Performance Monitors Extension is not implemented, this field is RES0.

In Non-secure state, HPMN divides the Performance Monitors counters as follows. If software is accessing Performance Monitors counter n then, in Non-secure state:

- If n is in the range 0<=n<HPMN, the counter is accessible from EL1 and EL2, and from EL0 if unprivileged access to the counters is enabled. PMCR.E enables the operation of counters in this range.
- If n is in the range HPMN<=n<PMCR.N, the counter is accessible only from EL2 and from Secure state. HDCR.HPME enables the operation of counters in this range.

If this field is set to 0, or to a value larger than PMCR.N, then the following CONSTRAINED UNPREDICTABLE behavior applies:

- The value returned by a direct read of HDCR.HPMN is UNKNOWN.
- Either:
  - An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if HDCR.HPMN is set to an UNKNOWN non-zero value less than PMCR.N.
  - All counters are reserved for EL2 use, meaning no counters are accessible from Non-secure EL1 and Non-secure EL0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to the value of PMCR.N.

Accessing the HDCR:

To access the HDCR:

```
MRC p15,4,<Rt>,c1,c1,1 ; Read HDCR into Rt
MCR p15,4,<Rt>,c1,c1,1 ; Write Rt to HDCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0001	0001	001

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.32 SDCR, Secure Debug Configuration Register

The SDCR characteristics are:

Purpose

When EL3 is implemented and can use AArch32, controls debug and performance monitors functionality in Secure state.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1 (NS)	EL1 (S)	EL2 (NS)
-	-	Trap	-

If EL3 is implemented and is using AArch64, any read or write to SDCR from Secure EL1 using AArch32 is trapped as an exception to EL3.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

This register is only accessible in Secure state.

AArch32 System register SDCR can be mapped to AArch64 System register MDCR_EL3, but this is not architecturally mandated.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

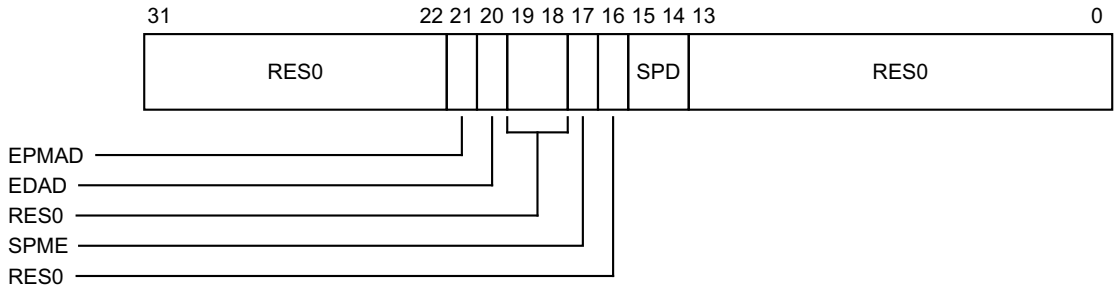
Attributes

SDCR is a 32-bit register.

Field descriptions

The SDCR bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



Bits [31:22]

Reserved, RES0.

EPMAD, bit [21]

External debug interface Performance Monitors registers disable. This disables access to these registers by an external debugger:

0 Access to Performance Monitors registers from external debugger is permitted.

1 Access to Performance Monitors registers from external debugger is disabled, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

If the Performance Monitors Extension is not implemented or does not support external debug interface accesses this bit is RES0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, if this field is implemented as an RW field, it resets to 0.

EDAD, bit [20]

External debug interface breakpoint and watchpoint register access disable. This disables access to these registers by an external debugger:

0 Access to breakpoint and watchpoint registers from external debugger is permitted.

1 Access to breakpoint and watchpoint registers from external debugger is disabled, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [19:18]

Reserved, RES0.

SPME, bit [17]

Secure Performance Monitors enable. This allows event counting in Secure state:

0 Event counting prohibited in Secure state, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

1 Event counting allowed in Secure state.

If the Performance Monitors Extension is not implemented, this field is RES0.

When this register has an architecturally-defined reset value, this field resets to 0.

Bit [16]

Reserved, RES0.

SPD, bits [15:14]

AArch32 Secure privileged debug. Enables or disables debug exceptions from Secure state, other than Software breakpoint instructions. Valid values for this field are:

00 Legacy mode. Debug exceptions from Secure EL1 are enabled by the authentication interface.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

`10` Secure privileged debug disabled. Debug exceptions from Secure EL1 are disabled.

`11` Secure privileged debug enabled. Debug exceptions from Secure EL1 are enabled.

Other values are reserved, and have the CONSTRAINED UNPREDICTABLE behavior that they must have the same behavior as `0b00`. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

If debug exceptions from Secure EL1 are enabled, then debug exceptions from Secure EL0 are also enabled.

Otherwise, debug exceptions from Secure EL0 are enabled only if SDER32_EL3.SUIDEN == 1.

Ignored in Non-secure state. Debug exceptions from Software breakpoint instruction debug events are always enabled.

When this register has an architecturally-defined reset value, this field resets to `0`.

Bits [13:0]

Reserved, RES0.

Accessing the SDCR:

To access the SDCR:

```
MRC p15,0,<Rt>,c1,c3,1 ; Read SDCR into Rt
MCR p15,0,<Rt>,c1,c3,1 ; Write Rt to SDCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0001	0011	001

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.3.33 SDER, Secure Debug Enable Register

The SDER characteristics are:

Purpose

Controls invasive and non-invasive debug in the Secure EL0 mode.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1 (NS)	EL1 (S)	EL2 (NS)
-	-	RW	-

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

This register is only accessible in Secure state.

AArch32 System register SDER is architecturally mapped to AArch64 System register SDER32_EL3.

If EL3 is not implemented and EL1 supports AArch32, SDER is implemented only if the implemented Security state is Secure state.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

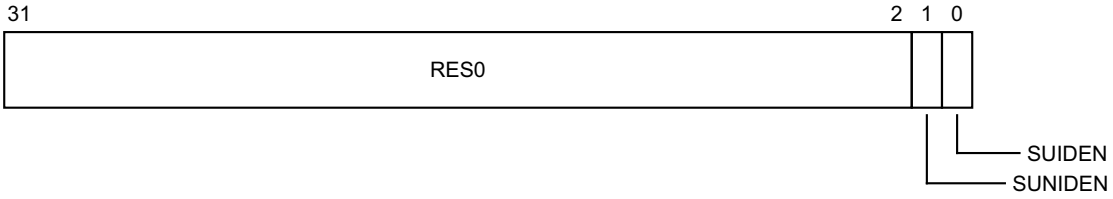
Attributes

SDER is a 32-bit register.

Field descriptions

The SDER bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



Bits [31:2]

Reserved, RES0.

SUNIDEN, bit [1]

Secure User Non-Invasive Debug Enable:

0 Performance Monitors event counting prohibited in Secure EL0 unless allowed by MDCR_EL3.SPME, SDCR.SPME, or the IMPLEMENTATION DEFINED authentication interface ExternalSecureNoninvasiveDebugEnabled().

1 Performance Monitors event counting allowed in Secure EL0.

When this register has an architecturally-defined reset value, this field resets to 0.

SUIDEN, bit [0]

Secure User Invasive Debug Enable:

0 Debug exceptions other than Software Breakpoint Instruction exceptions from Secure EL0 are disabled, unless enabled by MDCR_EL3.SPD32 or SDCR.SPD.

1 Debug exceptions from Secure EL0 are enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the SDER:

To access the SDER:

```
MRC p15,0,<Rt>,c1,c1,1 ; Read SDER into Rt
MCR p15,0,<Rt>,c1,c1,1 ; Write Rt to SDER
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0001	0001	001

G6.4 Performance Monitors registers

This section lists the Performance Monitors registers in AArch32.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.4.1 PMCCFILTR, Performance Monitors Cycle Count Filter Register

The PMCCFILTR characteristics are:

Purpose

Determines the modes in which the Cycle Counter, PMCCNTR, increments.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RW	RW	RW

PMCCFILTR can also be accessed by using PMXEVTYPER with PMSELR.SEL set to `0b11111`.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL3.TPM==1, accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If PMUSERENR.EN==0, accesses to this register from PL0 are trapped to Undefined mode.

If PMUSERENR_EL0.EN==0, accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCCFILTR is architecturally mapped to AArch64 System register PMCCFILTR_EL0.

AArch32 System register PMCCFILTR is architecturally mapped to External register PMCCFILTR_EL0.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

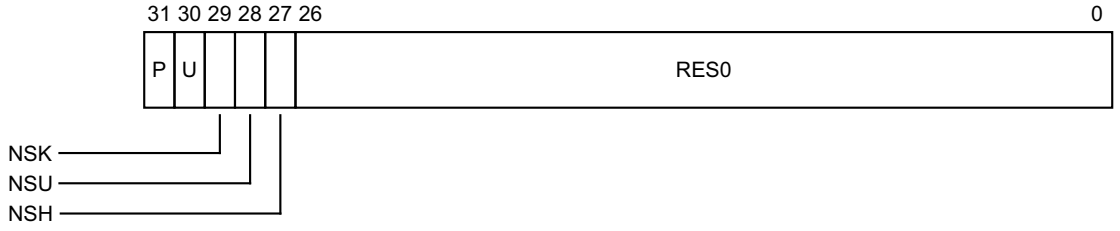
Attributes

PMCCFILTR is a 32-bit register.

Field descriptions

The PMCCFILTR bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



P, bit [31]

EL1 modes filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

`0` Count cycles in EL1.

`1` Do not count cycles in EL1.

When this register has an architecturally-defined reset value, this field resets to `0`.

U, bit [30]

EL0 filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

`0` Count cycles in EL0.

`1` Do not count cycles in EL0.

When this register has an architecturally-defined reset value, this field resets to `0`.

NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Non-secure EL1 are counted.

Otherwise, cycles in Non-secure EL1 are not counted.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to `0`.

NSU, bit [28]

Non-secure User mode filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, cycles in Non-secure EL0 are counted.

Otherwise, cycles in Non-secure EL0 are not counted.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to `0`.

NSH, bit [27]

Non-secure Hyp modes filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

`0` Do not count cycles in EL2.

`1` Count cycles in EL2.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to `0`.

Bits [26:0]

Reserved, RES0.

Non-Confidential - Beta

Accessing the PMCCFILTR:

To access the PMCCFILTR:

```
MRC p15,0,<Rt>,c14,c15,7 ; Read PMCCFILTR into Rt
MCR p15,0,<Rt>,c14,c15,7 ; Write Rt to PMCCFILTR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	1111	111

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.4.2 PMCCNTR, Performance Monitors Cycle Count Register

The PMCCNTR characteristics are:

Purpose

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles. See *Time as measured by the Performance Monitors cycle counter* on page D5-1751 for more information.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RW	RW	RW

The PMCR.{LC, D} bits configure whether PMCCNTR increments every clock cycle, or once every 64 clock cycles.

PMCCFILTR determines the modes and states in which the PMCCNTR can increment.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL3.TPM==1, accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If PMUSERENR.CR==0, and PMUSERENR.EN==0, read accesses to this register from PL0 are trapped to Undefined mode.

If PMUSERENR_EL0.CR==0, and PMUSERENR_EL0.EN==0, read accesses to this register from PL0 are trapped to EL1.

If PMUSERENR.EN==0, write accesses to this register from PL0 are trapped to Undefined mode.

If PMUSERENR_EL0.EN==0, write accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCCNTR is architecturally mapped to AArch64 System register PMCCNTR_EL0.

AArch32 System register PMCCNTR is architecturally mapped to External register PMCCNTR_EL0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions. This means that it is CONSTRAINED UNPREDICTABLE whether or not PMCCNTR continues to increment when clocks are stopped by WFI and WFE instructions.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

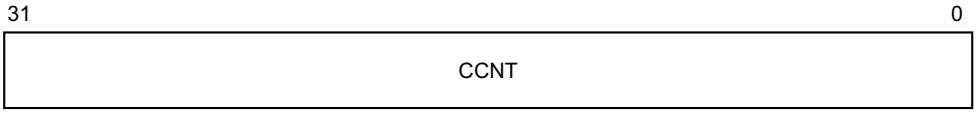
Attributes

PMCCNTR is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, accesses read and write bits [31:0] and do not modify bits [63:32].

Field descriptions

The PMCCNTR bit assignments are:

When accessing as a 32-bit register:



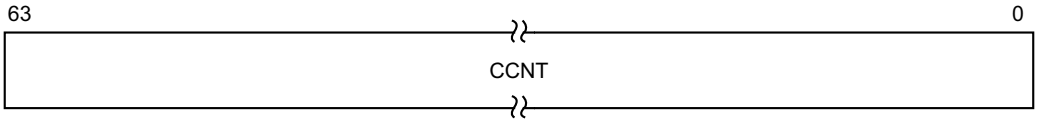
CCNT, bits [31:0]

Cycle count. Depending on the values of PMCR.{LC,D}, this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to PMCR.C sets this field to 0.

When accessing as a 64-bit register:



CCNT, bits [63:0]

Cycle count. Depending on the values of PMCR.{LC,D}, this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to PMCR.C sets this field to 0.

Accessing the PMCCNTR:

To access the PMCCNTR when accessing as a 32-bit register:

```
MRC p15,0,<Rt>,c9,c13,0 ; Read PMCCNTR[31:0] into Rt
MCR p15,0,<Rt>,c9,c13,0 ; Write Rt to PMCCNTR[31:0]. PMCCNTR[63:32] are unchanged
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1101	000

To access the PMCCNTR when accessing as a 64-bit register:

```
MRRC p15,0,<Rt>,<Rt2>,c9 ; Read PMCCNTR[31:0] into Rt and PMCCNTR[63:32] into Rt2
MCRR p15,0,<Rt>,<Rt2>,c9 ; Write Rt to PMCCNTR[31:0] and Rt2 to PMCCNTR[63:32]
```

Register access is encoded as follows:

coproc	opc1	CRm
1111	0000	1001

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.4.3 PMCEID0, Performance Monitors Common Event Identification register 0

The PMCEID0 characteristics are:

Purpose

Defines which common architectural and common microarchitectural feature events are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RO	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TPM==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TPM==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL3.TPM==1, read accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If HSTR.T9==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If HSTR_EL2.T9==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

If PMUSERENR.EN==0, read accesses to this register from PL0 are trapped to Undefined mode.

If PMUSERENR_EL0.EN==0, read accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCEID0 is architecturally mapped to AArch64 System register PMCEID0_EL0.

AArch32 System register PMCEID0 is architecturally mapped to External register PMCEID0_EL0.

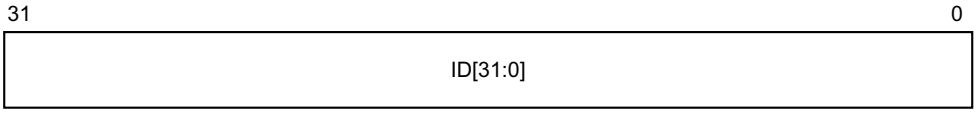
Attributes

PMCEID0 is a 32-bit register.

Field descriptions

The PMCEID0 bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



ID[31:0], bits [31:0]

PMCEID0[n] maps to event n. For a list of event numbers and descriptions, see *Events, event numbers, and mnemonics* on page D5-1764.

For each bit:

`0` The common event is not implemented.

`1` The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

Accessing the PMCEID0:

To access the PMCEID0:

```
MRC p15,0,<Rt>,c9,c12,6 ; Read PMCEID0 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	110

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.4.4 PMCEID1, Performance Monitors Common Event Identification register 1

The PMCEID1 characteristics are:

Purpose

Defines which common architectural and common microarchitectural feature events are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RO	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TPM==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TPM==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL3.TPM==1, read accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If HSTR.T9==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If HSTR_EL2.T9==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

If PMUSERENR.EN==0, read accesses to this register from PL0 are trapped to Undefined mode.

If PMUSERENR_EL0.EN==0, read accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCEID1 is architecturally mapped to AArch64 System register PMCEID1_EL0.

AArch32 System register PMCEID1 is architecturally mapped to External register PMCEID1_EL0.

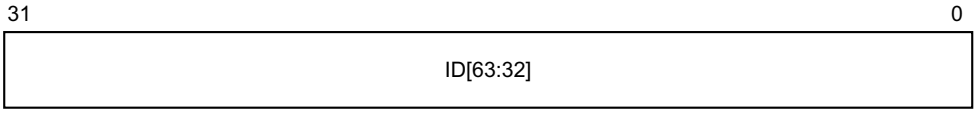
Attributes

PMCEID1 is a 32-bit register.

Field descriptions

The PMCEID1 bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



ID[63:32], bits [31:0]

PMCEID1[n] maps to event (n + 32). For a list of event numbers and descriptions, see *Events, event numbers, and mnemonics* on page D5-1764.

For each bit:

`0` The common event is not implemented.

`1` The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

Accessing the PMCEID1:

To access the PMCEID1:

```
MRC p15,0,<Rt>,c9,c12,7 ; Read PMCEID1 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	111

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.4.5 PMCNTENCLR, Performance Monitors Count Enable Clear register

The PMCNTENCLR characteristics are:

Purpose

Disables the Cycle Count Register, PMCCNTR, and any implemented event counters PMEVCNTR<x>. Reading this register shows which counters are enabled.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RW	RW	RW

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMCNTENCLR. See the description of the Px bit.

PMCNTENCLR is used in conjunction with the PMCNTENSET register.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL3.TPM==1, accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If PMUSERENR.EN==0, accesses to this register from PL0 are trapped to Undefined mode.

If PMUSERENR_EL0.EN==0, accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCNTENCLR is architecturally mapped to AArch64 System register PMCNTENCLR_EL0.

AArch32 System register PMCNTENCLR is architecturally mapped to External register PMCNTENCLR_EL0.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

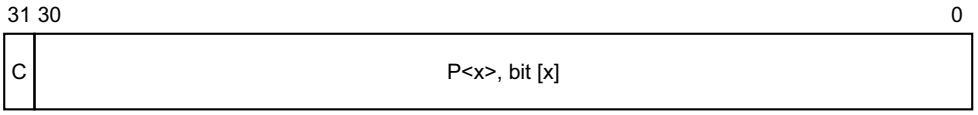
Attributes

PMCNTENCLR is a 32-bit register.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Field descriptions

The PMCNTENCLR bit assignments are:



C, bit [31]

PMCCNTR disable bit. Disables the cycle counter register. Possible values are:

`0` When read, means the cycle counter is disabled. When written, has no effect.

`1` When read, means the cycle counter is enabled. When written, disables the cycle counter.

P<x>, bit [x], for x = 0 to 30

Event counter disable bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN. Otherwise, N is the value in PMCR.N.

Possible values of each bit are:

`0` When read, means that PMEVCNTR<x> is disabled. When written, has no effect.

`1` When read, means that PMEVCNTR<x> is enabled. When written, disables PMEVCNTR<x>.

Accessing the PMCNTENCLR:

To access the PMCNTENCLR:

```
MRC p15,0,<Rt>,c9,c12,2 ; Read PMCNTENCLR into Rt
MCR p15,0,<Rt>,c9,c12,2 ; Write Rt to PMCNTENCLR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	010

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.4.6 PMCNTENSET, Performance Monitors Count Enable Set register

The PMCNTENSET characteristics are:

Purpose

Enables the Cycle Count Register, PMCCNTR, and any implemented event counters PMEVCNTR<x>. Reading this register shows which counters are enabled.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RW	RW	RW

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMCNTENSET. See the description of the Px bit.

PMCNTENSET is used in conjunction with the PMCNTENCLR register.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL3.TPM==1, accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If PMUSERENR.EN==0, accesses to this register from PL0 are trapped to Undefined mode.

If PMUSERENR_EL0.EN==0, accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCNTENSET is architecturally mapped to AArch64 System register PMCNTENSET_EL0.

AArch32 System register PMCNTENSET is architecturally mapped to External register PMCNTENSET_EL0.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

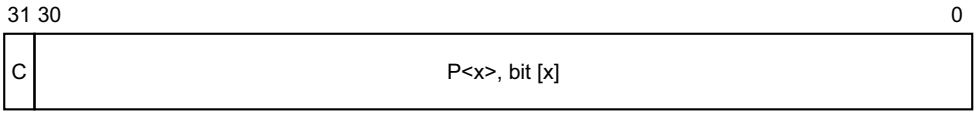
Attributes

PMCNTENSET is a 32-bit register.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Field descriptions

The PMCNTENSET bit assignments are:



C, bit [31]

PMCCNTR enable bit. Enables the cycle counter register. Possible values are:

`0` When read, means the cycle counter is disabled. When written, has no effect.

`1` When read, means the cycle counter is enabled. When written, enables the cycle counter.

P<x>, bit [x], for x = 0 to 30

Event counter enable bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN. Otherwise, N is the value in PMCR.N.

Possible values of each bit are:

`0` When read, means that PMEVCNTR<x> is disabled. When written, has no effect.

`1` When read, means that PMEVCNTR<x> event counter is enabled. When written, enables PMEVCNTR<x>.

Accessing the PMCNTENSET:

To access the PMCNTENSET:

```
MRC p15,0,<Rt>,c9,c12,1 ; Read PMCNTENSET into Rt
MCR p15,0,<Rt>,c9,c12,1 ; Write Rt to PMCNTENSET
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	001

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.4.7 PMCR, Performance Monitors Control Register

The PMCR characteristics are:

Purpose

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RW	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL3.TPM==1, accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If HDCR.TPMCR==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TPMCR==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If PMUSERENR.EN==0, accesses to this register from PL0 are trapped to Undefined mode.

If PMUSERENR_EL0.EN==0, accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCR is architecturally mapped to AArch64 System register PMCR_EL0.

AArch32 System register PMCR[6:0] is architecturally mapped to External register PMCR_EL0[6:0].

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

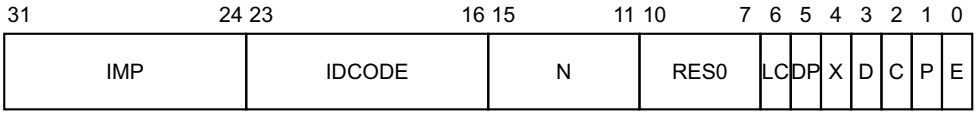
Non-Confidential - Beta

Attributes

PMCR is a 32-bit register.

Field descriptions

The PMCR bit assignments are:



IMP, bits [31:24]

Implementer code. This field is RO with an IMPLEMENTATION DEFINED value.

The implementer codes are allocated by ARM. Values have the same interpretation as bits [31:24] of the MIDR.

IDCODE, bits [23:16]

Identification code. This field is RO with an IMPLEMENTATION DEFINED value.

Each implementer must maintain a list of identification codes that is specific to the implementer. A specific implementation is identified by the combination of the implementer code and the identification code.

N, bits [15:11]

Number of event counters. A RO field that indicates the number counters implemented. A value of `0b00000` in this field indicates that only the Cycle Count Register PMCCNTR is implemented.

The value of this field is the number of event counters implemented. This value is in the range of `0b00000`, in which case only the PMCCNTR is implemented, to `0b11111`, which indicates that the PMCCNTR and 31 event counters are implemented.

In an implementation that includes EL2, reads of this field from Non-secure EL1 and Non-secure EL0 return the value of HDCR.HPMN.

Bits [10:7]

Reserved, RES0.

LC, bit [6]

Long cycle counter enable. Determines which PMCCNTR bit generates an overflow recorded by PMOVSR[31].

`0` Cycle counter overflow on increment that changes PMCCNTR[31] from 1 to 0.

`1` Cycle counter overflow on increment that changes PMCCNTR[63] from 1 to 0.

ARM deprecates use of PMCR.LC = 0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

DP, bit [5]

Disable cycle counter when event counting is prohibited. The possible values of this bit are:

`0` PMCCNTR, if enabled, counts when event counting is prohibited.

`1` PMCCNTR does not count when event counting is prohibited.

Event counting is prohibited when ProfilingProhibited(IsSecure(),PSTATE.EL) == TRUE.

This bit is RW.

If EL3 is not implemented, this field is RES0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to `0`.

X, bit [4]

Enable export of events in an IMPLEMENTATION DEFINED event stream. The possible values of this bit are:

`0` Do not export events.

`1` Export events where not prohibited.

This bit is used to permit events to be exported to another debug device, such as an OPTIONAL trace macrocell, over an event bus. If the implementation does not include such an event bus, this bit is RAZ/WI.

This bit does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the PE.

If the implementation does not include an exported event stream, this bit is RAZ/WI. Otherwise this bit is RW.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to `0`.

D, bit [3]

Clock divider. The possible values of this bit are:

`0` When enabled, PMCCNTR counts every clock cycle.

`1` When enabled, PMCCNTR counts once every 64 clock cycles.

This bit is RW.

If PMCR.LC == 1, this bit is ignored and the cycle counter counts every clock cycle.

ARM deprecates use of PMCR.D = 1.

When this register has an architecturally-defined reset value, this field resets to `0`.

C, bit [2]

Cycle counter reset. This bit is WO. The effects of writing to this bit are:

`0` No action.

`1` Reset PMCCNTR to zero.

This bit is always RAZ.

Resetting PMCCNTR does not clear the PMCCNTR overflow bit to 0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

P, bit [1]

Event counter reset. This bit is WO. The effects of writing to this bit are:

`0` No action.

`1` Reset all event counters accessible in the current EL, not including PMCCNTR, to zero.

This bit is always RAZ.

In Non-secure EL0 and EL1, if EL2 is implemented, a write of 1 to this bit does not reset event counters that HDCR.HPMN reserves for EL2 use.

In EL2 and EL3, a write of 1 to this bit resets all the event counters.

Resetting the event counters does not clear any overflow bits to 0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

E, bit [0]

Enable. The possible values of this bit are:

`0` All counters, including PMCCNTR, are disabled.

`1` All counters are enabled by PMCNTENSET.

This bit is RW.

If EL2 is implemented, this bit does not affect the operation of event counters that HDCR.HPMN reserves for EL2 use.

When this register has an architecturally-defined reset value, this field resets to `0`.

Accessing the PMCR:

To access the PMCR:

```
MRC p15,0,<Rt>,c9,c12,0 ; Read PMCR into Rt
MCR p15,0,<Rt>,c9,c12,0 ; Write Rt to PMCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.4.8 PMEVCNTR<n>, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n> characteristics are:

Purpose

Holds event counter n, which counts events, where n is 0 to 30.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RW	RW	RW

This register can be read at EL0 when PMUSERENR.EN or PMUSERENR.ER is set to 1, and can be written at EL0 when PMUSERENR.ER is set to 1.

PMEVCNTR<n> can also be accessed by using PMXEVCNTR with PMSELR.SEL set to n.

If <n> is greater than or equal to the number of accessible counters, reads and writes of PMEVCNTR<n> are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- In Non-secure state, for an access from PL1 or a permitted access from PL0, if PMSELR.SEL, or PMSELR_EL0.SEL if EL1 is using AArch64, is greater than or equal to the number of accessible counters but is less than the number of implemented counters, the register access is trapped to EL2. Accesses from PL0 are permitted when:
  - EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
  - EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

Note

In an implementation that includes EL2, in Non-secure state at EL0 and EL1:

- If EL2 is using AArch32, HDCR.HPMN identifies the number of accessible counters.
- If EL2 is using AArch64, MDCR_EL2.HPMN identifies the number of accessible counters.

Otherwise, the number of accessible counters is the number of implemented counters.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

If MDCR_EL3.TPM==1, accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If PMUSERENR.EN==0, and PMUSERENR.ER==0, read accesses to this register from PL0 are trapped to Undefined mode.

If PMUSERENR.EN==0, write accesses to this register from PL0 are trapped to Undefined mode.

If PMUSERENR_EL0.EN==0, write accesses to this register from PL0 are trapped to EL1.

If PMUSERENR_EL0.ER==0, and PMUSERENR_EL0.EN==0, read accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMEVCNTR<n> is architecturally mapped to AArch64 System register PMEVCNTR<n>_EL0.

AArch32 System register PMEVCNTR<n> is architecturally mapped to External register PMEVCNTR<n>_EL0.

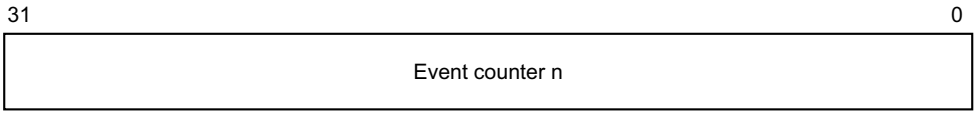
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMEVCNTR<n> is a 32-bit register.

Field descriptions

The PMEVCNTR<n> bit assignments are:



Bits [31:0]

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

Accessing the PMEVCNTR<n>:

To access the PMEVCNTR<n>:

```
MRC p15,0,<Rt>,c14,<CRm>,<opc2> ; Read PMEVCNTR<n> into Rt, where n is in the range 0 to 30
MCR p15,0,<Rt>,c14,<CRm>,<opc2> ; Write Rt to PMEVCNTR<n>, where n is in the range 0 to 30
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	10:n<4:3>	n<2:0>

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.4.9 PMEVTYPER<n>, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<n> characteristics are:

Purpose

Configures event counter n, where n is 0 to 30.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RW	RW	RW

This register is accessible at EL0 when PMUSERENR.EN is set to 1.

PMEVTYPER<n> can also be accessed by using PMXEVTYPER with PMSELR.SEL set to n.

If <n> is greater or equal to the number of accessible counters, reads and writes of PMEVTYPER<n> are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a `NOP`.
- In Non-secure state, for an access from PL1 or a permitted access from PL0, if PMSELR.SEL, or PMSELR_EL0.SEL if EL1 is using AArch64, is greater than or equal to the number of accessible counters but is less than the number of implemented counters, the register access is trapped to EL2. Accesses from PL0 are permitted when:
  - EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
  - EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

Note

In an implementation that includes EL2, in Non-secure state at EL0 and EL1:

- If EL2 is using AArch32, HDCR.HPMN identifies the number of accessible counters.
- If EL2 is using AArch64, MDCR_EL2.HPMN identifies the number of accessible counters.

Otherwise, the number of accessible counters is the number of implemented counters.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

If MDCR_EL3.TPM==1, accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If PMUSERENR.EN==0, accesses to this register from PL0 are trapped to Undefined mode.

If PMUSERENR_EL0.EN==0, accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMEVTYPER<n> is architecturally mapped to AArch64 System register PMEVTYPER<n>_EL0.

AArch32 System register PMEVTYPER<n> is architecturally mapped to External register PMEVTYPER<n>_EL0.

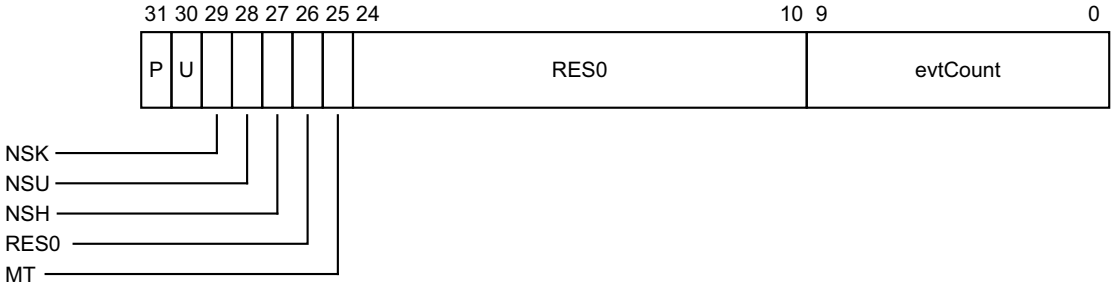
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMEVTYPER<n> is a 32-bit register.

Field descriptions

The PMEVTYPER<n> bit assignments are:



P, bit [31]

EL1 modes filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

`0` Count events in EL1.

`1` Do not count events in EL1.

U, bit [30]

EL0 filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

`0` Count events in EL0.

`1` Do not count events in EL0.

NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Non-secure EL1 are counted.

Otherwise, events in Non-secure EL1 are not counted.

NSU, bit [28]

Non-secure User mode filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, events in Non-secure EL0 are counted.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Otherwise, events in Non-secure EL0 are not counted.

NSH, bit [27]

Non-secure Hyp modes filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0 Do not count events in EL2.

1 Count events in EL2.

Bit [26]

Reserved, RES0.

MT, bit [25]

Multithreading. When the implementation is multi-threaded, the valid values for this bit are:

0 Count events only on controlling PE.

1 Count events from any PE with the same affinity at level 1 and above as this PE.

When the implementation is not multi-threaded, this bit is RES0.

Note

- Events from a different thread of a multi-threaded implementation are not Attributable to the thread counting the event.
- An implementation is described as multi-threaded when the lowest level of affinity consists of logical PEs that are implemented using a multi-threading type approach. That is, the performance of PEs at the lowest affinity level is highly interdependent. On such an implementation, the value of MPIDR.MT, when read at the highest implemented Exception level, is 1.

Bits [24:10]

Reserved, RES0.

evtCount, bits [9:0]

Event to count. The event number of the event that is counted by event counter PMEVCNTR<n>.

Software must program this field with an event defined by the processor or a common event defined by the architecture.

If evtCount is programmed to an event that is reserved or not implemented, the behavior depends on the event type.

For common architectural and microarchitectural events:

- No events are counted.
- The value read back on evtCount is the value written.

For IMPLEMENTATION DEFINED events:

- It is UNPREDICTABLE what event, if any, is counted. UNPREDICTABLE in this case means the event must not expose privileged information.
- The value read back on evtCount is an UNKNOWN value with the same effect.

ARM recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATION DEFINED events, then no event is counted and the value read back on evtCount is the value written.

Accessing the PMEVTYPER<n>:

To access the PMEVTYPER<n>:

```
MRC p15,0,<Rt>,c14,<CRm>,<opc2> ; Read PMEVTYPER<n> into Rt, where n is in the range 0 to 30
MCR p15,0,<Rt>,c14,<CRm>,<opc2> ; Write Rt to PMEVTYPER<n>, where n is in the range 0 to 30
```

G6.4.10 PMINTENCLR, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR characteristics are:

Purpose

Disables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR, and the event counters PMEVCNTR<n>. Reading the register shows which overflow interrupt requests are enabled.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMINTENCLR. See the description of the P<x> bit.

PMINTENCLR is used in conjunction with the PMINTENSET register.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TPM==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TPM==1, accesses to this register from PL1 and PL2 are trapped to EL3.

If HSTR.T9==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If HSTR_EL2.T9==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMINTENCLR is architecturally mapped to AArch64 System register PMINTENCLR_EL1.

AArch32 System register PMINTENCLR is architecturally mapped to External register PMINTENCLR_EL1.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

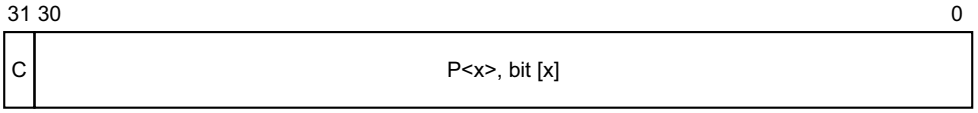
Attributes

PMINTENCLR is a 32-bit register.

Field descriptions

The PMINTENCLR bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



C, bit [31]

PMCCNTR overflow interrupt request disable bit. Possible values are:

`0` When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

`1` When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request.

P<x>, bit [x], for x = 0 to 30

Event counter overflow interrupt request disable bit for PMEVCNTR<x>.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN. Otherwise, N is the value in PMCR.N.

Bits [30:N] are RAZ/WI.

Possible values are:

`0` When read, means that the PMEVCNTR<x> event counter interrupt request is disabled. When written, has no effect.

`1` When read, means that the PMEVCNTR<x> event counter interrupt request is enabled. When written, disables the PMEVCNTR<x> interrupt request.

Accessing the PMINTENCLR:

To access the PMINTENCLR:

```
MRC p15,0,<Rt>,c9,c14,2 ; Read PMINTENCLR into Rt
MCR p15,0,<Rt>,c9,c14,2 ; Write Rt to PMINTENCLR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1110	010

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.4.11 PMINTENSET, Performance Monitors Interrupt Enable Set register

The PMINTENSET characteristics are:

Purpose

Enables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR, and the event counters PMEVCNTR<n>. Reading the register shows which overflow interrupt requests are enabled.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMINTENSET. See the description of the P<x> bit.

PMINTENSET is used in conjunction with the PMINTENCLR register.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TPM==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL1 are trapped to EL2.

If MDCR_EL3.TPM==1, accesses to this register from PL1 and PL2 are trapped to EL3.

If HSTR.T9==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If HSTR_EL2.T9==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMINTENSET is architecturally mapped to AArch64 System register PMINTENSET_EL1.

AArch32 System register PMINTENSET is architecturally mapped to External register PMINTENSET_EL1.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

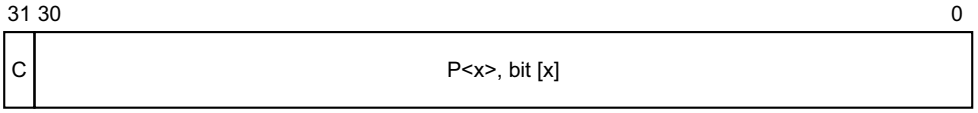
Attributes

PMINTENSET is a 32-bit register.

Field descriptions

The PMINTENSET bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



C, bit [31]

PMCCNTR overflow interrupt request enable bit. Possible values are:

`0` When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

`1` When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request.

P<x>, bit [x], for x = 0 to 30

Event counter overflow interrupt request enable bit for PMEVCNTR<x>.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN. Otherwise, N is the value in PMCR.N.

Bits [30:N] are RAZ/WI.

Possible values are:

`0` When read, means that the PMEVCNTR<x> event counter interrupt request is disabled. When written, has no effect.

`1` When read, means that the PMEVCNTR<x> event counter interrupt request is enabled. When written, enables the PMEVCNTR<x> interrupt request.

Accessing the PMINTENSET:

To access the PMINTENSET:

```
MRC p15,0,<Rt>,c9,c14,1 ; Read PMINTENSET into Rt
MCR p15,0,<Rt>,c9,c14,1 ; Write Rt to PMINTENSET
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1110	001

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.4.12 PMOVSR, Performance Monitors Overflow Flag Status Register

The PMOVSR characteristics are:

Purpose

Contains the state of the overflow bit for the Cycle Count Register, PMCCNTR, and each of the implemented event counters PMEVCNTR<x>. Writing to this register clears these bits.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RW	RW	RW

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMOVSR. See the description of the Px bit.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL3.TPM==1, accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If PMUSERENR.EN==0, accesses to this register from PL0 are trapped to Undefined mode.

If PMUSERENR_EL0.EN==0, accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMOVSR is architecturally mapped to AArch64 System register PMOVSCLR_EL0.

AArch32 System register PMOVSR is architecturally mapped to External register PMOVSCLR_EL0.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

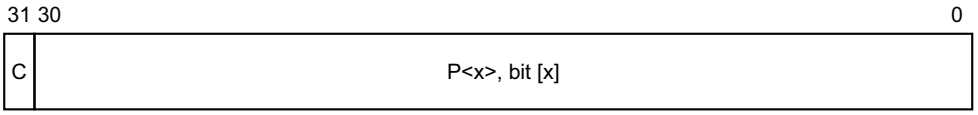
Attributes

PMOVSR is a 32-bit register.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Field descriptions

The PMOVSR bit assignments are:



C, bit [31]

PMCCNTR overflow bit. Possible values are:

`0` When read, means the cycle counter has not overflowed. When written, has no effect.

`1` When read, means the cycle counter has overflowed. When written, clears the overflow bit to 0.

PMCR.LC is used to control from which bit of PMCCNTR (bit 31 or bit 63) an overflow is detected.

P<x>, bit [x], for x = 0 to 30

Event counter overflow clear bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN. Otherwise, N is the value in PMCR.N.

Possible values of each bit are:

`0` When read, means that PMEVCNTR<x> has not overflowed. When written, has no effect.

`1` When read, means that PMEVCNTR<x> has overflowed. When written, clears the PMEVCNTR<x> overflow bit to 0.

Accessing the PMOVSR:

To access the PMOVSR:

```
MRC p15,0,<Rt>,c9,c12,3 ; Read PMOVSR into Rt
MCR p15,0,<Rt>,c9,c12,3 ; Write Rt to PMOVSR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	011

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.4.13 PMOVSSET, Performance Monitors Overflow Flag Status Set register

The PMOVSSET characteristics are:

Purpose

Sets the state of the overflow bit for the Cycle Count Register, PMCCNTR, and each of the implemented event counters PMEVCNTR<x>.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RW	RW	RW

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMOVSSET. See the description of the Px bit.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL3.TPM==1, accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If PMUSERENR.EN==0, accesses to this register from PL0 are trapped to Undefined mode.

If PMUSERENR_EL0.EN==0, accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMOVSSET is architecturally mapped to AArch64 System register PMOVSSET_EL0.

AArch32 System register PMOVSSET is architecturally mapped to External register PMOVSSET_EL0.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

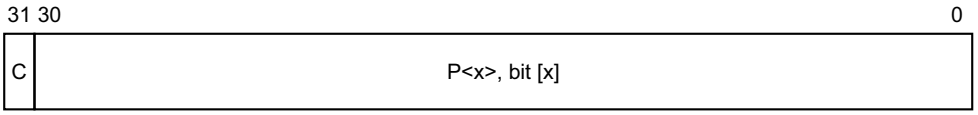
Attributes

PMOVSSET is a 32-bit register.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Field descriptions

The PMOVSSET bit assignments are:



C, bit [31]

PMCCNTR overflow bit. Possible values are:

`0` When read, means the cycle counter has not overflowed. When written, has no effect.

`1` When read, means the cycle counter has overflowed. When written, sets the overflow bit to 1.

P<x>, bit [x], for x = 0 to 30

Event counter overflow set bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN. Otherwise, N is the value in PMCR.N.

Possible values are:

`0` When read, means that PMEVCNTR<x> has not overflowed. When written, has no effect.

`1` When read, means that PMEVCNTR<x> has overflowed. When written, sets the PMEVCNTR<x> overflow bit to 1.

Accessing the PMOVSSET:

To access the PMOVSSET:

```
MRC p15,0,<Rt>,c9,c14,3 ; Read PMOVSSET into Rt
MCR p15,0,<Rt>,c9,c14,3 ; Write Rt to PMOVSSET
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1110	011

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.4.14 PMSELR, Performance Monitors Event Counter Selection Register

The PMSELR characteristics are:

Purpose

Selects the current event counter PMEVCNTR<x> or the cycle counter, CCNT.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RW	RW	RW

PMSELR is used in conjunction with PMXEVTYPER to determine the event that increments a selected event counter, and the modes and states in which the selected counter increments.

It is also used in conjunction with PMXEVCNTR, to determine the value of a selected event counter.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL3.TPM==1, accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If PMUSERENR.EN==0, and PMUSERENR.ER==0, accesses to this register from PL0 are trapped to Undefined mode.

If PMUSERENR_EL0.EN==0, and PMUSERENR_EL0.ER==0, accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMSELR is architecturally mapped to AArch64 System register PMSELR_EL0.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

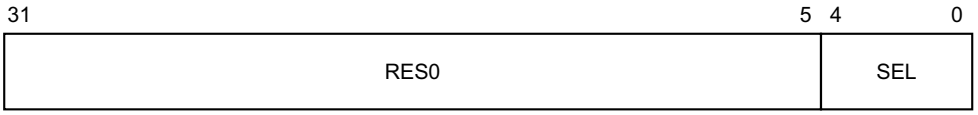
Attributes

PMSELR is a 32-bit register.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Field descriptions

The PMSELR bit assignments are:



Bits [31:5]

Reserved, RES0.

SEL, bits [4:0]

Selects event counter, PMEVCNTR<x>, where x is the value held in this field. This value identifies which event counter is accessed when a subsequent access to PMXEVTYPER or PMXEVCNTR occurs.

This field can take any value from 0 (`0b00000`) to (PMCR.N)-1, or 31 (`0b11111`).

When PMSELR.SEL is `0b11111` it selects the cycle counter and:

- A read of the PMXEVTYPER returns the value of PMCCFILTR.
- A write of the PMXEVTYPER writes to PMCCFILTR.
- A read or write of PMXEVCNTR has CONSTRAINED UNPREDICTABLE effects, that can be one of the following:
  - Access to PMXEVCNTR is UNDEFINED.
  - Access to PMXEVCNTR behaves as a NOP.
  - Access to PMXEVCNTR behaves as if the register is RAZ/WI.
  - Access to PMXEVCNTR behaves as if the PMSELR.SEL field contains an UNKNOWN value.

If this field is set to a value greater than or equal to the number of implemented counters, but not equal to 31, the results of access to PMXEVTYPER or PMXEVCNTR are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Access to PMXEVTYPER or PMXEVCNTR is UNDEFINED.
- Access to PMXEVTYPER or PMXEVCNTR behaves as a NOP.
- Access to PMXEVTYPER or PMXEVCNTR behaves as if the register is RAZ/WI.
- Access to PMXEVTYPER or PMXEVCNTR behaves as if the PMSELR.SEL field contains an UNKNOWN value.
- Access to PMXEVTYPER or PMXEVCNTR behaves as if the PMSELR.SEL field contains `0b11111`.

Accessing the PMSELR:

To access the PMSELR:

```
MRC p15,0,<Rt>,c9,c12,5 ; Read PMSELR into Rt
MCR p15,0,<Rt>,c9,c12,5 ; Write Rt to PMSELR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	101

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.4.15 PMSWINC, Performance Monitors Software Increment register

The PMSWINC characteristics are:

Purpose

Increments a counter that is configured to count the Software increment event, event `0x00`.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-WO	Config-WO	WO	WO	WO	WO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-WO	WO	WO

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMSWINC. See the description of the Px bit.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TPM==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TPM==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL3.TPM==1, write accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If HSTR.T9==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If HSTR_EL2.T9==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.

If PMUSERENR.EN==0, and PMUSERENR.SW==0, write accesses to this register from PL0 are trapped to Undefined mode.

If PMUSERENR_EL0.EN==0, and PMUSERENR_EL0.SW==0, write accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMSWINC is architecturally mapped to AArch64 System register PMSWINC_EL0.

AArch32 System register PMSWINC is architecturally mapped to External register PMSWINC_EL0.

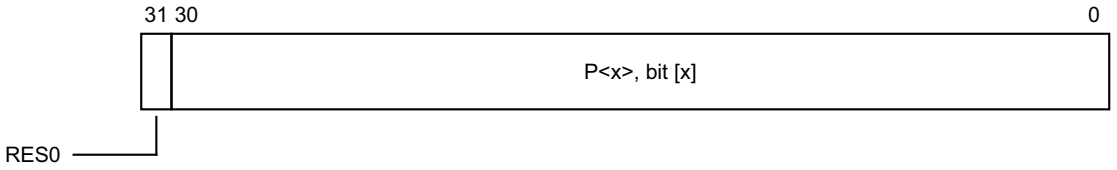
Attributes

PMSWINC is a 32-bit register.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Field descriptions

The PMSWINC bit assignments are:



Bit [31]

Reserved, RES0.

P<x>, bit [x], for x = 0 to 30

Event counter software increment bit for PMEVCNTR<x>.

Bits [30:N] are WI.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN. Otherwise, N is the value in PMCR.N.

The effects of writing to this bit are:

0 No action. The write to this bit is ignored.

1 If PMEVCNTR<x> is enabled and configured to count the software increment event, increments PMEVCNTR<x> by 1. If PMEVCNTR<x> is disabled, or not configured to count the software increment event, the write to this bit is ignored.

Accessing the PMSWINC:

To access the PMSWINC:

```
MCR p15,0,<Rt>,c9,c12,4 ; Write Rt to PMSWINC
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	100

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.4.16 PMUSERENR, Performance Monitors User Enable Register

The PMUSERENR characteristics are:

Purpose

Enables or disables User mode access to the Performance Monitors.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RO	RO	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
RO	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL3.TPM==1, accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMUSERENR is architecturally mapped to AArch64 System register PMUSERENR_EL0.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

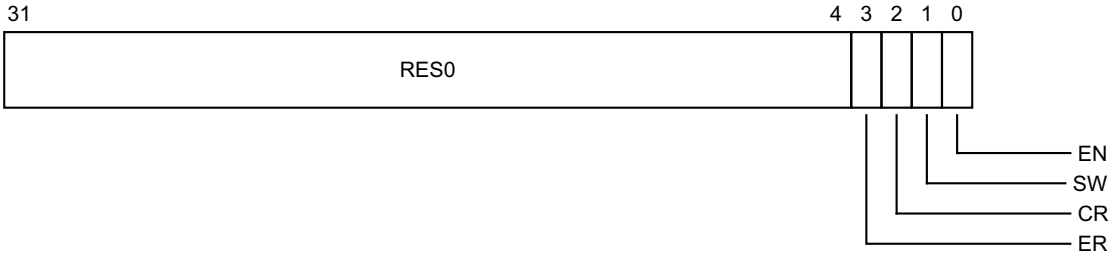
Attributes

PMUSERENR is a 32-bit register.

Field descriptions

The PMUSERENR bit assignments are:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



Bits [31:4]

Reserved, RES0.

ER, bit [3]

Event counter read trap control:

0 PL0 reads of the PMXEVCNTR and PMEVCNTR<n>, and PL0 read/write access to the PMSELR, are trapped to Undefined mode if PMUSERENR.EN is also 0.

1 PL0 reads of the PMXEVCNTR and PMEVCNTR<n>, and PL0 read/write access to the PMSELR, are not trapped to Undefined mode.

When this register has an architecturally-defined reset value, this field resets to 0.

CR, bit [2]

Cycle counter read trap control:

0 PL0 reads of the PMCCNTR are trapped to Undefined mode if PMUSERENR.EN is also 0.

1 PL0 reads of the PMCCNTR are not trapped to Undefined mode.

When this register has an architecturally-defined reset value, this field resets to 0.

SW, bit [1]

Software increment write trap control:

0 PL0 writes to the PMSWINC are trapped to Undefined mode if PMUSERENR.EN is also 0.

1 PL0 writes to the PMSWINC are not trapped to Undefined mode.

When this register has an architecturally-defined reset value, this field resets to 0.

EN, bit [0]

Traps PL0 accesses to the Performance Monitors registers to Undefined mode:

0 PL0 accesses to the Performance Monitors registers are trapped to Undefined mode.

1 PL0 accesses to the Performance Monitors registers are not trapped to Undefined mode. Software can access all PMU registers at PL0.

Note

- The PMUSERENR is register is always RO at EL0 and not trapped by this bit.
- PL0 cannot read or write PMINTENSET and PMINTENCLR.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the PMUSERENR:

To access the PMUSERENR:

```
MRC p15,0,<Rt>,c9,c14,0 ; Read PMUSERENR into Rt
MCR p15,0,<Rt>,c9,c14,0 ; Write Rt to PMUSERENR
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1110	000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.4.17 PMXEVCNTR, Performance Monitors Selected Event Count Register

The PMXEVCNTR characteristics are:

Purpose

Reads or writes the value of the selected event counter, PMEVCNTR<x>. PMSELR.SEL determines which event counter is selected.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RW	RW	RW

If PMSELR.SEL is greater than or equal to the number of accessible counters then reads and writes of PMXEVCNTR are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- Accesses to the register behave as if PMSELR.SEL has an UNKNOWN value less than the number of counters accessible at the current Exception level and Security state.
- Accesses to the register behave as if PMSELR.SEL is 31.
- In Non-secure state, for an access from PL1 or a permitted access from PL0, if PMSELR.SEL, or PMSELR_EL0.SEL if EL1 is using AArch64, is greater than or equal to the number of accessible counters but is less than the number of implemented counters, the register access is trapped to EL2. Accesses from PL0 are permitted when:
  - EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
  - EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

Note

In an implementation that includes EL2, in Non-secure state at EL0 and EL1:

- If EL2 is using AArch32, HDCR.HPMN identifies the number of accessible counters.
- If EL2 is using AArch64, MDCR_EL2.HPMN identifies the number of accessible counters.

Otherwise, the number of accessible counters is the number of implemented counters.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL3.TPM==1, accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If PMUSERENR.EN==0, and PMUSERENR.ER==0, read accesses to this register from PL0 are trapped to Undefined mode.

If PMUSERENR.EN==0, write accesses to this register from PL0 are trapped to Undefined mode.

If PMUSERENR_EL0.EN==0, write accesses to this register from PL0 are trapped to EL1.

If PMUSERENR_EL0.ER==0, and PMUSERENR_EL0.EN==0, read accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMXEVCNTR is architecturally mapped to AArch64 System register PMXEVCNTR_EL0.

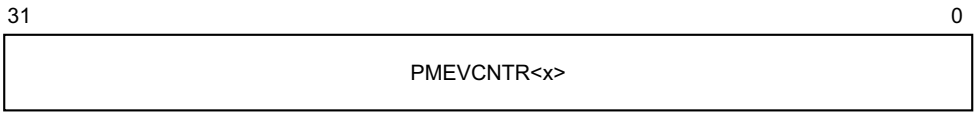
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMXEVCNTR is a 32-bit register.

Field descriptions

The PMXEVCNTR bit assignments are:



PMEVCNTR<x>, bits [31:0]

Value of the selected event counter, PMEVCNTR<x>, where x is the value stored in PMSELR.SEL.

Accessing the PMXEVCNTR:

To access the PMXEVCNTR:

```
MRC p15,0,<Rt>,c9,c13,2 ; Read PMXEVCNTR into Rt
MCR p15,0,<Rt>,c9,c13,2 ; Write Rt to PMXEVCNTR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1101	010

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.4.18 PMXEVTYPER, Performance Monitors Selected Event Type Register

The PMXEVTYPER characteristics are:

Purpose

When PMSELR.SEL selects an event counter, this accesses a PMEVTYPER<n> register. When PMSELR.SEL selects the cycle counter, this accesses PMCCFILTR.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RW	RW	RW

If PMSELR.SEL is greater than or equal to the number of accessible counters then reads and writes of PMXEVTYPER are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- Accesses to the register behave as if PMSELR.SEL has an UNKNOWN value less than the number of counters accessible at the current Exception level and Security state.
- Accesses to the register behave as if PMSELR.SEL is 31.
- In Non-secure state, for an access from PL1 or a permitted access from PL0, if PMSELR.SEL, or PMSELR_EL0.SEL if EL1 is using AArch64, is greater than or equal to the number of accessible counters but is less than the number of implemented counters, the register access is trapped to EL2. Accesses from PL0 are permitted when:
  - EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
  - EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

Note

In an implementation that includes EL2, in Non-secure state at EL0 and EL1:

- If EL2 is using AArch32, HDCR.HPMN identifies the number of accessible counters.
- If EL2 is using AArch64, MDCR_EL2.HPMN identifies the number of accessible counters.

Otherwise, the number of accessible counters is the number of implemented counters.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If HDCR.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

If MDCR_EL2.TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If MDCR_EL3.TPM==1, accesses to this register from PL0, PL1, and PL2 are trapped to EL3.

If HSTR.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If HSTR_EL2.T9==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If PMUSERENR.EN==0, accesses to this register from PL0 are trapped to Undefined mode.

If PMUSERENR_EL0.EN==0, accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMXEVTYPER is architecturally mapped to AArch64 System register PMXEVTYPER_EL0.

When the value of PMSELR.SEL is 31, to select the cycle counter, RW fields in this register have defined reset values that apply only when the PE resets into an Exception level that is using AArch32. See PMCCFILTR for the reset values.

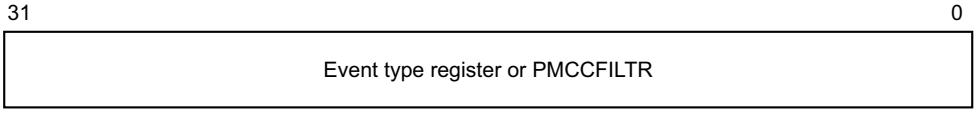
Otherwise, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN. This applies whenever PMSELR.SEL selects an event counter.

Attributes

PMXEVTYPER is a 32-bit register.

Field descriptions

The PMXEVTYPER bit assignments are:



Bits [31:0]

Event type register or PMCCFILTR.

When PMSELR.SEL == 31, this register accesses PMCCFILTR.

Otherwise, this register accesses PMEVTYPER<n> where n is the value in PMSELR.SEL.

Accessing the PMXEVTYPER:

To access the PMXEVTYPER:

```
MRC p15,0,<Rt>,c9,c13,1 ; Read PMXEVTYPER into Rt
MCR p15,0,<Rt>,c9,c13,1 ; Write Rt to PMXEVTYPER
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1101	001

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.5 Generic Timer registers

This section lists the Generic Timer registers in AArch32.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.5.1 CNTFRQ, Counter-timer Frequency register

The CNTFRQ characteristics are:

Purpose

This register is provided so that software can discover the frequency of the system counter. It must be programmed with this value as part of system initialization. The value of the register is not interpreted by hardware.

Usage constraints

If EL1 is the highest exception level implemented and is using AArch32, this register is accessible as follows:

EL0	EL1
Config-RO	RW

If EL2 is the highest exception level implemented and is using AArch32, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RO	RO	RW

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RW	RW

If EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RO	RO	RO

Can only be written at the highest Exception level implemented. For example, if EL3 is the highest implemented Exception level, CNTFRQ can only be written at EL3.

If EL3 is using AArch64, write accesses to CNTFRQ from Secure EL1 modes are UNDEFINED.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If CNTKCTL.PL0PCTEN==0, and CNTKCTL.PL0VCTEN==0, read accesses to this register from PL0 are trapped to Undefined mode.

If CNTKCTL_EL1.EL0PCTEN==0, and CNTKCTL_EL1.EL0VCTEN==0, read accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

AArch32 System register CNTFRQ is architecturally mapped to AArch64 System register CNTFRQ_EL0.

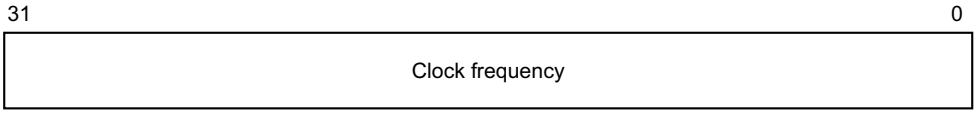
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTFRQ is a 32-bit register.

Field descriptions

The CNTFRQ bit assignments are:



Bits [31:0]

Clock frequency. Indicates the system counter clock frequency, in Hz.

Accessing the CNTFRQ:

To access the CNTFRQ:

```
MRC p15,0,<Rt>,c14,c0,0 ; Read CNTFRQ into Rt
MCR p15,0,<Rt>,c14,c0,0 ; Write Rt to CNTFRQ
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	0000	000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.5.2 CNTHCTL, Counter-timer Hyp Control register

The CNTHCTL characteristics are:

Purpose

Controls the generation of an event stream from the physical counter, and access from Non-secure EL1 modes to the physical counter and the Non-secure EL1 physical timer.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	-

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	RW

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch32 System register CNTHCTL is architecturally mapped to AArch64 System register CNTHCTL_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

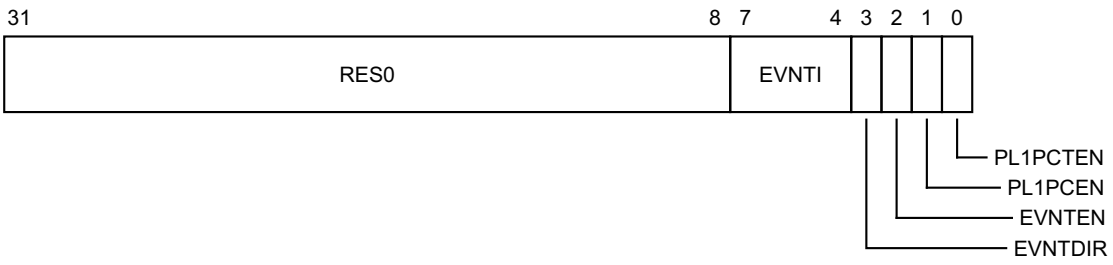
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHCTL is a 32-bit register.

Field descriptions

The CNTHCTL bit assignments are:



Bits [31:8]

Reserved, RES0.

EVNTI, bits [7:4]

Selects which bit (0 to 15) of the corresponding counter register (CNTPCT or CNTVCT) is the trigger for the event stream generated from that counter, when that stream is enabled.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

EVNTDIR, bit [3]

Controls which transition of the counter register (CNTPCT or CNTVCT) trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

0 A 0 to 1 transition of the trigger bit triggers an event.

1 A 1 to 0 transition of the trigger bit triggers an event.

EVNTEN, bit [2]

Enables the generation of an event stream from the corresponding counter:

0 Disables the event stream.

1 Enables the event stream.

PL1PCEN, bit [1]

Traps Non-secure EL0 and EL1 accesses to the physical timer registers to Hyp mode.

0 Non-secure EL0 and EL1 accesses to the CNTP_CTL, CNTP_CVAL, and CNTP_TVAL are trapped to Hyp mode.

1 Non-secure EL0 and EL1 accesses to the CNTP_CTL, CNTP_CVAL, and CNTP_TVAL are not trapped to Hyp mode.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

PL1PCTEN, bit [0]

Traps Non-secure EL0 and EL1 accesses to the physical counter register to Hyp mode.

0 Non-secure EL0 and EL1 accesses to the CNTPCT are trapped to Hyp mode.

1 Non-secure EL0 and EL1 accesses to the CNTPCT are not trapped to Hyp mode.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

Accessing the CNTHCTL:

To access the CNTHCTL:

```
MRC p15,4,<Rt>,c14,c1,0 ; Read CNTHCTL into Rt
MCR p15,4,<Rt>,c14,c1,0 ; Write Rt to CNTHCTL
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1110	0001	000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.5.3 CNTHP_CTL, Counter-timer Hyp Physical Timer Control register

The CNTHP_CTL characteristics are:

Purpose

Control register for the Hyp mode physical timer.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	-

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	RW

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch32 System register CNTHP_CTL is architecturally mapped to AArch64 System register CNTHP_CTL_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

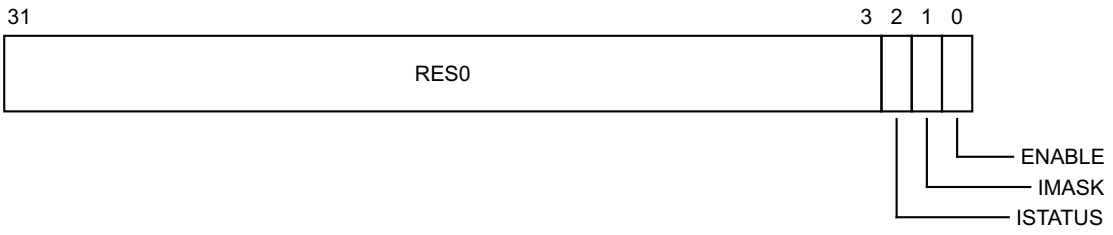
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHP_CTL is a 32-bit register.

Field descriptions

The CNTHP_CTL bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is asserted:

0 Timer condition is not asserted.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

1 Timer condition is asserted.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer value meets the condition for the timer output to be asserted. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer output signal is asserted.

For more information see *Operation of the CompareValue views of the timers* on page D6-1798 and *Operation of the TimerValue views of the timers* on page D6-1799.

This bit is read-only.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

IMASK, bit [1]

Timer output signal mask bit. Permitted values are:

0 Timer output signal is not masked.

1 Timer output signal is masked.

For more information, see the description of the ISTATUS bit.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

ENABLE, bit [0]

Enables the timer. Permitted values are:

0 Timer disabled.

1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHP_TVAL continues to count down.

Note

Disabling the output signal might be a power-saving option.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the CNTHP_CTL:

To access the CNTHP_CTL:

```
MRC p15,4,<Rt>,c14,c2,1 ; Read CNTHP_CTL into Rt
MCR p15,4,<Rt>,c14,c2,1 ; Write Rt to CNTHP_CTL
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1110	0010	001

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.5.4 CNTHP_CVAL, Counter-timer Hyp Physical CompareValue register

The CNTHP_CVAL characteristics are:

Purpose

Holds the compare value for the Hyp mode physical timer.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	-

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	RW

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch32 System register CNTHP_CVAL is architecturally mapped to AArch64 System register CNTHP_CVAL_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

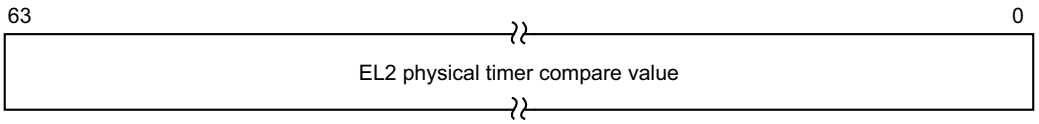
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHP_CVAL is a 64-bit register.

Field descriptions

The CNTHP_CVAL bit assignments are:



Bits [63:0]

EL2 physical timer compare value.

Accessing the CNTHP_CVAL:

To access the CNTHP_CVAL:

```
MRRC p15,6,<Rt>,<Rt2>,c14 ; Read CNTHP_CVAL[31:0] into Rt and CNTHP_CVAL[63:32] into Rt2
MCRR p15,6,<Rt>,<Rt2>,c14 ; Write Rt to CNTHP_CVAL[31:0] and Rt2 to CNTHP_CVAL[63:32]
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Register access is encoded as follows:

coproc	opc1	CRm
1111	0110	1110

Non-Confidential - Beta

G6.5.5 CNTHP_TVAL, Counter-timer Hyp Physical Timer TimerValue register

The CNTHP_TVAL characteristics are:

Purpose

Holds the timer value for the Hyp mode physical timer.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	-

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	RW

Where the value of CNTHP_CTL.ENABLE is 0:

- A write to CNTHP_TVAL updates the register
- The value held in CNTHP_TVAL continues to decrement
- A read of CNTHP_TVAL returns an UNKNOWN value.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch32 System register CNTHP_TVAL is architecturally mapped to AArch64 System register CNTHP_TVAL_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

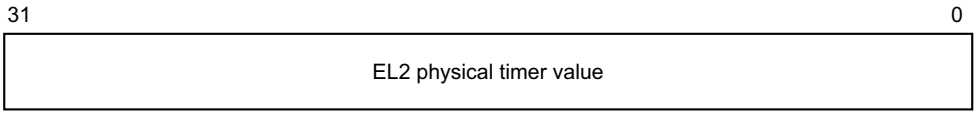
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHP_TVAL is a 32-bit register.

Field descriptions

The CNTHP_TVAL bit assignments are:



Bits [31:0]

EL2 physical timer value.

Accessing the CNTHP_TVAL:

To access the CNTHP_TVAL:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

```
MRC p15,4,<Rt>,c14,c2,0 ; Read CNTHP_TVAL into Rt
MCR p15,4,<Rt>,c14,c2,0 ; Write Rt to CNTHP_TVAL
```

Register access is encoded as follows:

1111	100	1110	0010	000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.5.6 CNTKCTL, Counter-timer Kernel Control register

The CNTKCTL characteristics are:

Purpose

Controls the generation of an event stream from the virtual counter, and access from EL0 modes to the physical counter, virtual counter, EL1 physical timers, and the virtual timer.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	RW	RW

Traps and Enables

There are no traps or enables affecting this register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTKCTL is architecturally mapped to AArch64 System register CNTKCTL_EL1.

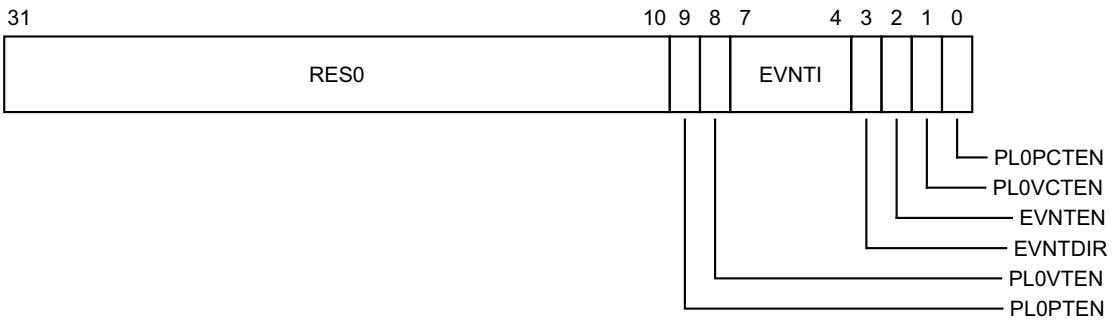
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTKCTL is a 32-bit register.

Field descriptions

The CNTKCTL bit assignments are:



Bits [31:10]

Reserved, RES0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

PL0PTEN, bit [9]

Traps PL0 accesses to the physical timer registers to Undefined mode.

0 PL0 accesses to the CNTP_CTL, CNTP_CVAL, and CNTP_TVAL registers are trapped to Undefined mode.

1 PL0 accesses to the CNTP_CTL, CNTP_CVAL, and CNTP_TVAL registers are not trapped to Undefined mode.

PL0VTEN, bit [8]

Traps PL0 accesses to the virtual timer registers to Undefined mode.

0 PL0 accesses to the CNTV_CTL, CNTV_CVAL, and CNTV_TVAL registers are trapped to Undefined mode.

1 PL0 accesses to the CNTV_CTL, CNTV_CVAL, and CNTV_TVAL registers are not trapped to Undefined mode.

EVNTI, bits [7:4]

Selects which bit (0 to 15) of the corresponding counter register (CNTPCT or CNTVCT) is the trigger for the event stream generated from that counter, when that stream is enabled.

EVNTDIR, bit [3]

Controls which transition of the counter register (CNTPCT or CNTVCT) trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

0 A 0 to 1 transition of the trigger bit triggers an event.

1 A 1 to 0 transition of the trigger bit triggers an event.

EVNTEN, bit [2]

Enables the generation of an event stream from the corresponding counter:

0 Disables the event stream.

1 Enables the event stream.

PL0VCTEN, bit [1]

Traps PL0 accesses to the frequency register and virtual counter register to Undefined mode.

0 PL0 accesses to the CNTVCT are trapped to Undefined mode.

PL0 accesses to the CNTFRQ register are trapped to Undefined mode, if CNTKCTL.PL0PCTEN is also 0.

1 PL0 accesses to the CNTFRQ and CNTVCT are not trapped to Undefined mode.

PL0PCTEN, bit [0]

Traps PL0 accesses to the frequency register and physical counter register to Undefined mode.

0 PL0 accesses to the CNTPCT are trapped to Undefined mode.

PL0 accesses to the CNTFRQ register are trapped to Undefined mode, if CNTKCTL.PL0VCTEN is also 0.

1 PL0 accesses to the CNTFRQ and CNTPCT are not trapped to Undefined mode.

Accessing the CNTKCTL:

To access the CNTKCTL:

```
MRC p15,0,<Rt>,c14,c1,0 ; Read CNTKCTL into Rt
MCR p15,0,<Rt>,c14,c1,0 ; Write Rt to CNTKCTL
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	0001	000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.

G6.5.7 CNTP_CTL, Counter-timer Physical Timer Control register

The CNTP_CTL characteristics are:

Purpose

Control register for the EL1 physical timer.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

CNTP_CTL(S) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	Config-RW	-	-	-	RW

CNTP_CTL(NS) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	-	Config-RW	RW	RW	-

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

CNTP_CTL is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RW	Config-RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If CNTHCTL.PL1PCEN==0, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If CNTHCTL_EL2.EL1PCEN==0, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If CNTKCTL.PL0PTEN==0, accesses to this register from PL0 are trapped to Undefined mode.

If CNTKCTL_EL1.EL0PTEN==0, accesses to this register from PL0 are trapped to EL1.

Configurations

AArch32 System register CNTP_CTL is architecturally mapped to AArch64 System register CNTP_CTL_EL0.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. If the PE resets into EL3 using AArch32 they apply only to the Secure instance of the register. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

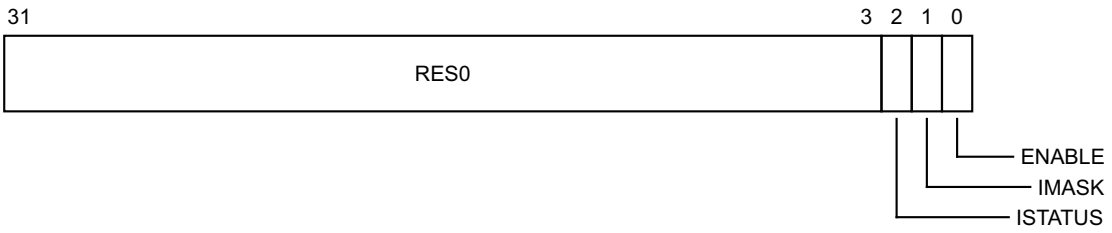
Attributes

CNTP_CTL is a 32-bit register.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Field descriptions

The CNTP_CTL bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is asserted:

`0` Timer condition is not asserted.

`1` Timer condition is asserted.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer value meets the condition for the timer output to be asserted. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer output signal is asserted.

For more information see *Operation of the CompareValue views of the timers* on page D6-1798 and *Operation of the TimerValue views of the timers* on page D6-1799.

This bit is read-only.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

IMASK, bit [1]

Timer output signal mask bit. Permitted values are:

`0` Timer output signal is not masked.

`1` Timer output signal is masked.

For more information, see the description of the ISTATUS bit.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

ENABLE, bit [0]

Enables the timer. Permitted values are:

`0` Timer disabled.

`1` Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTP_TVAL continues to count down.

Note

Disabling the output signal might be a power-saving option.

When this register has an architecturally-defined reset value, this field resets to `0`.

Accessing the CNTP_CTL:

To access the CNTP_CTL:

Non-Confidential - Beta

G6.5.8 CNTP_CVAL, Counter-timer Physical Timer CompareValue register

The CNTP_CVAL characteristics are:

Purpose

Holds the compare value for the EL1 physical timer.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

CNTP_CVAL(S) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	Config-RW	-	-	-	RW

CNTP_CVAL(NS) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	-	Config-RW	RW	RW	-

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

CNTP_CVAL is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RW	Config-RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If CNTHCTL.PL1PCEN==0, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If CNTHCTL_EL2.EL1PCEN==0, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If CNTKCTL.PL0PTEN==0, accesses to this register from PL0 are trapped to Undefined mode.

If CNTKCTL_EL1.EL0PTEN==0, accesses to this register from PL0 are trapped to EL1.

Configurations

AArch32 System register CNTP_CVAL is architecturally mapped to AArch64 System register CNTP_CVAL_EL0.

RW fields in this register reset to architecturally UNKNOWN values.

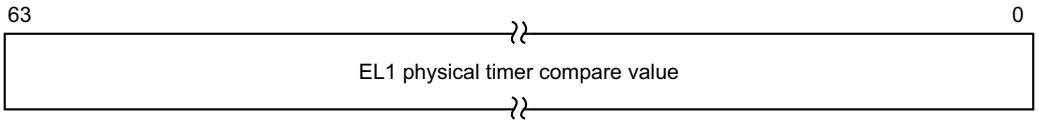
Attributes

CNTP_CVAL is a 64-bit register.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Field descriptions

The CNTP_CVAL bit assignments are:



Bits [63:0]

EL1 physical timer compare value.

Accessing the CNTP_CVAL:

To access the CNTP_CVAL:

```
MRRC p15,2,<Rt>,<Rt2>,c14 ; Read CNTP_CVAL[31:0] into Rt and CNTP_CVAL[63:32] into Rt2
MCRR p15,2,<Rt>,<Rt2>,c14 ; Write Rt to CNTP_CVAL[31:0] and Rt2 to CNTP_CVAL[63:32]
```

Register access is encoded as follows:

coproc	opc1	CRm
1111	0010	1110

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.5.9 CNTP_TVAL, Counter-timer Physical Timer TimerValue register

The CNTP_TVAL characteristics are:

Purpose

Holds the timer value for the EL1 physical timer. This provides a 32-bit downcounter.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

CNTP_TVAL(S) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	Config-RW	-	-	-	RW

CNTP_TVAL(NS) is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	-	Config-RW	RW	RW	-

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

CNTP_TVAL is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RW	Config-RW	RW

Where the value of CNTP_CTL.ENABLE is 0:

- A write to CNTP_TVAL updates the register
- The value held in CNTP_TVAL continues to decrement
- A read of CNTP_TVAL returns an UNKNOWN value.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If CNTHCTL.PL1PCEN==0, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If CNTHCTL_EL2.EL1PCEN==0, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

If CNTKCTL.PL0PTEN==0, accesses to this register from PL0 are trapped to Undefined mode.

If CNTKCTL_EL1.EL0PTEN==0, accesses to this register from PL0 are trapped to EL1.

Configurations

AArch32 System register CNTP_TVAL is architecturally mapped to AArch64 System register CNTP_TVAL_EL0.

RW fields in this register reset to architecturally UNKNOWN values.

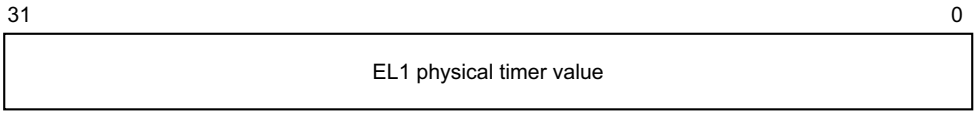
Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Attributes

CNTP_TVAL is a 32-bit register.

Field descriptions

The CNTP_TVAL bit assignments are:



Bits [31:0]

EL1 physical timer value.

Accessing the CNTP_TVAL:

To access the CNTP_TVAL:

```
MRC p15,0,<Rt>,c14,c2,0 ; Read CNTP_TVAL into Rt
MCR p15,0,<Rt>,c14,c2,0 ; Write Rt to CNTP_TVAL
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	0010	000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.5.10 CNTPCT, Counter-timer Physical Count register

The CNTPCT characteristics are:

Purpose

Holds the 64-bit physical count value.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	Config-RO	RO	RO	RO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RO	Config-RO	RO

When CNTKCTL.EL0PCTEN is set to 1, if CNTPCT is accessible from EL1 in the current Security state then it is also accessible from EL0 in that Security state.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If CNTHCTL.PL1PCTEN==0, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.

If CNTHCTL_EL2.EL1PCTEN==0, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.

If CNTKCTL.PL0PCTEN==0, read accesses to this register from PL0 are trapped to Undefined mode.

If CNTKCTL_EL1.EL0PCTEN==0, read accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

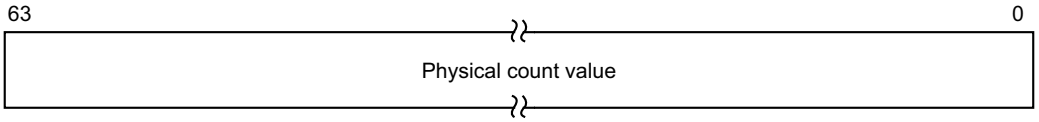
AArch32 System register CNTPCT is architecturally mapped to AArch64 System register CNTPCT_EL0.

Attributes

CNTPCT is a 64-bit register.

Field descriptions

The CNTPCT bit assignments are:



Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Bits [63:0]

Physical count value.

Accessing the CNTPCT:

To access the CNTPCT:

```
MRRC p15,0,<Rt>,<Rt2>,c14 ; Read CNTPCT[31:0] into Rt and CNTPCT[63:32] into Rt2
```

Register access is encoded as follows:

coproc	opc1	CRm
1111	0000	1110

Non-Confidential - Beta

G6.5.11 CNTV_CTL, Counter-timer Virtual Timer Control register

The CNTV_CTL characteristics are:

Purpose

Control register for the virtual timer.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RW	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If CNTKCTL.PL0VTEN==0, accesses to this register from PL0 are trapped to Undefined mode.

If CNTKCTL_EL1.EL0VTEN==0, accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTV_CTL is architecturally mapped to AArch64 System register CNTV_CTL_EL0.

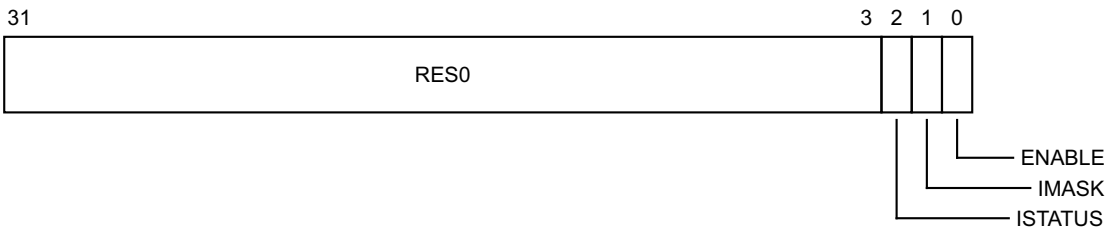
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTV_CTL is a 32-bit register.

Field descriptions

The CNTV_CTL bit assignments are:



Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is asserted:

0 Timer condition is not asserted.

1 Timer condition is asserted.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer value meets the condition for the timer output to be asserted. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer output signal is asserted.

For more information see *Operation of the CompareValue views of the timers* on page D6-1798 and *Operation of the TimerValue views of the timers* on page D6-1799.

This bit is read-only.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

IMASK, bit [1]

Timer output signal mask bit. Permitted values are:

0 Timer output signal is not masked.

1 Timer output signal is masked.

For more information, see the description of the ISTATUS bit.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

ENABLE, bit [0]

Enables the timer. Permitted values are:

0 Timer disabled.

1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTV_TVAL continues to count down.

Note

Disabling the output signal might be a power-saving option.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the CNTV_CTL:

To access the CNTV_CTL:

```
MRC p15,0,<Rt>,c14,c3,1 ; Read CNTV_CTL into Rt
MCR p15,0,<Rt>,c14,c3,1 ; Write Rt to CNTV_CTL
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	0011	001

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

G6.5.12 CNTV_CVAL, Counter-timer Virtual Timer CompareValue register

The CNTV_CVAL characteristics are:

Purpose

Holds the compare value for the virtual timer.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RW	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If CNTKCTL.PL0VTEN==0, accesses to this register from PL0 are trapped to Undefined mode.

If CNTKCTL_EL1.EL0VTEN==0, accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTV_CVAL is architecturally mapped to AArch64 System register CNTV_CVAL_EL0.

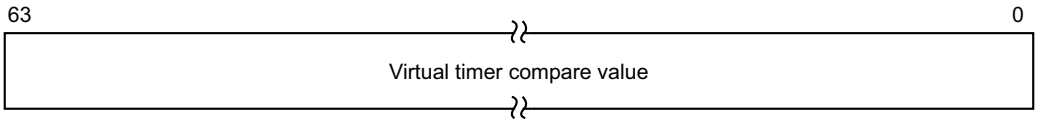
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTV_CVAL is a 64-bit register.

Field descriptions

The CNTV_CVAL bit assignments are:



Bits [63:0]

Virtual timer compare value.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the CNTV_CVAL:

To access the CNTV_CVAL:

```
MRRC p15,3,<Rt>,<Rt2>,c14 ; Read CNTV_CVAL[31:0] into Rt and CNTV_CVAL[63:32] into Rt2
MCRR p15,3,<Rt>,<Rt2>,c14 ; Write Rt to CNTV_CVAL[31:0] and Rt2 to CNTV_CVAL[63:32]
```

Register access is encoded as follows:

Non-Confidential - Beta

G6.5.13 CNTV_TVAL, Counter-timer Virtual Timer TimerValue register

The CNTV_TVAL characteristics are:

Purpose

Holds the timer value for the virtual timer.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RW	RW	RW

Where the value of CNTV_CTL.ENABLE is 0:

- A write to CNTV_TVAL updates the register
- The value held in CNTV_TVAL continues to decrement
- A read of CNTV_TVAL returns an UNKNOWN value.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If CNTKCTL.PL0VTEN==0, accesses to this register from PL0 are trapped to Undefined mode.

If CNTKCTL_EL1.EL0VTEN==0, accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTV_TVAL is architecturally mapped to AArch64 System register CNTV_TVAL_EL0.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTV_TVAL is a 32-bit register.

Field descriptions

The CNTV_TVAL bit assignments are:

G6.5.14 CNTVCT, Counter-timer Virtual Count register

The CNTVCT characteristics are:

Purpose

Holds the 64-bit virtual count value.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
Config-RO	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3674 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478 for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If CNTKCTL.PL0VCTEN==0, read accesses to this register from PL0 are trapped to Undefined mode.

If CNTKCTL_EL1.EL0VCTEN==0, read accesses to this register from PL0 are trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTVCT is architecturally mapped to AArch64 System register CNTVCT_EL0.

The virtual count value is equal to the physical count value visible in CNTPCT minus the virtual offset visible in CNTVOFF.

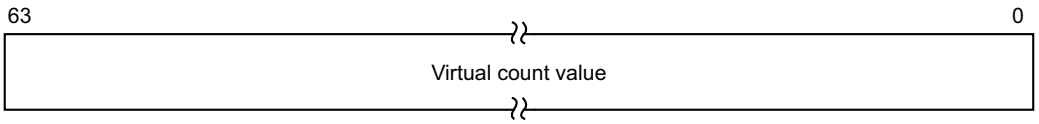
When EL2 is not implemented, CNTVOFF is RES0, and the value of this register is the same as the value of CNTPCT.

Attributes

CNTVCT is a 64-bit register.

Field descriptions

The CNTVCT bit assignments are:



Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Bits [63:0]

Virtual count value.

Accessing the CNTVCT:

To access the CNTVCT:

```
MRRC p15,1,<Rt>,<Rt2>,c14 ; Read CNTVCT[31:0] into Rt and CNTVCT[63:32] into Rt2
```

Register access is encoded as follows:

Non-Confidential - Beta

G6.5.15 CNTVOFF, Counter-timer Virtual Offset register

The CNTVOFF characteristics are:

Purpose

Holds the 64-bit virtual offset. This is the offset between the physical count value visible in CNTPCT and the virtual count value visible in CNTVCT.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL2 (NS)	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	-

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

EL0	EL1	EL2 (NS)
-	-	RW

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch32 System register CNTVOFF is architecturally mapped to AArch64 System register CNTVOFF_EL2.

If EL2 is not implemented, this register is RES0 from EL3 and the virtual counter uses a fixed virtual offset to zero.

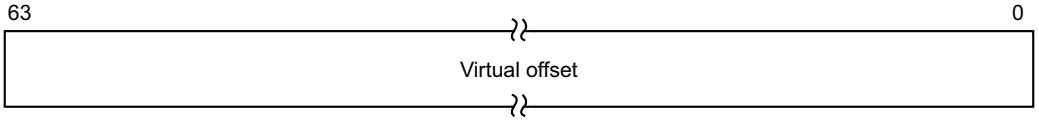
When EL2 is implemented and can use AArch32, on a reset into an Exception level that is using AArch32 this register resets to an IMPLEMENTATION DEFINED value that might be UNKNOWN.

Attributes

CNTVOFF is a 64-bit register.

Field descriptions

The CNTVOFF bit assignments are:



Bits [63:0]

Virtual offset.

Accessing the CNTVOFF:

To access the CNTVOFF:

```
MRRC p15,4,<Rt>,<Rt2>,c14 ; Read CNTVOFF[31:0] into Rt and CNTVOFF[63:32] into Rt2
MCRR p15,4,<Rt>,<Rt2>,c14 ; Write Rt to CNTVOFF[31:0] and Rt2 to CNTVOFF[63:32]
```

Part H
External Debug

Chapter H1
Introduction to External Debug

This chapter introduces the external debug components of ARMv8. It contains the following sections:

- *Introduction to external debug* on page H1-4690.
- *External debug* on page H1-4691.

Note

For information about self-hosted debug, see Chapter D2 *AArch64 Self-hosted Debug* and Chapter G2 *AArch32 Self-hosted Debug*.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H1.1 Introduction to external debug

ARMv8 supports both:

Self-hosted debug

The PE itself hosts a debugger. That is, developers developing software to run on the PE use debugger software running on the same PE.

External debug

The debugger is external to the PE. The debugging might be either on-chip, for example in a second PE, or off-chip, for example a JTAG debugger. External debug is particularly useful for:

- Hardware bring-up. That is, debugging during development when a system is first powered up and not all of the software functionality is available.
- PEs that are deeply embedded inside systems.

To support external debug, the ARM architecture defines required features that are called *external debug features*.

Note

Definition of a debugger

When the description of external debug in this part of the manual describes a *debugger* as controlling external debug this might be a second on-chip PE or a processor in an off-chip device such as a JTAG debugger.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H1.2 External debug

The following halting debug events are available in ARMv8:

- *Halting Step debug events* on page H3-4736:
  - The debugger can use this resource to make the PE step through code one line at a time.
- *Halt Instruction debug event* on page H3-4746:
  - This might occur when software executes the Halting software breakpoint instruction, `HLT`.
- *Exception Catch debug event* on page H3-4747:
  - This can be programmed to occur on all entries to a given Exception level.
- *External Debug Request debug event* on page H3-4750:
  - An embedded cross-trigger can signal this debug event.
- *OS Unlock Catch debug event* on page H3-4751:
  - This might occur when the state of the OS Lock changes from locked to unlocked.
- *Reset Catch debug events* on page H3-4752:
  - This might occur when the PE exits reset state.
- *Software Access debug event* on page H3-4753:
  - This can be programmed to occur when software tries to access the Breakpoint Value registers, the Breakpoint Control registers, the Watchpoint value registers, or the Watchpoint Control registers. It caused a trap to Debug state.

Halting debug events allow an external debugger to halt the PE. Breakpoints and watchpoints can also halt the PE. The PE then enters Debug state. When the PE is in Debug state:

- It stops executing instructions from the location indicated by the program counter, and is instead controlled through the external debug interface.
- The *Instruction Transfer Register,* ITR, passes instructions to the PE to execute in Debug state:
  - The ITR contains a single register, EDITR, and associated flow-control flags.
- The *Debug Communications Channel*, DCC, passes data between the PE and the debugger:
  - The DCC includes the data transfer registers, DTRRX and DTRTX, and associated flow-control flags.
  - Although the DCC is an essential part of Debug state operation, it can also be used in Non-debug state.
- The PE cannot service any interrupts in Debug state.

Chapter H2 *Debug State* describes Debug state in more detail.

Chapter H2
Debug State

This chapter describes Debug state. It contains the following sections:

- *About Debug state* on page H2-4694.
- *Halting the PE on debug events* on page H2-4695.
- *Entering Debug state* on page H2-4702.
- *Behavior in Debug state* on page H2-4705.
- *Exiting Debug state* on page H2-4730.

Note

Table K13-1 on page K13-5568 disambiguates the general register references used in this chapter.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H2.1 About Debug state

In external debug, debug events allow an external debugger to halt the PE. The PE then enters Debug state. When the PE is in Debug state:

- It stops executing instructions from the location indicated by the program counter, and is instead controlled through the external debug interface.
- The *Instruction Transfer Register,* ITR, passes instructions to the PE to execute in Debug state.
- The *Debug Communications Channel*, DCC, passes data between the PE and the debugger.

The PE cannot service any interrupts in Debug state.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H2.2 Halting the PE on debug events

For details of debug events see *Introduction to Halting debug events* on page H3-4734 and *Breakpoint and Watchpoint debug events* on page H2-4696.

On a debug event, the PE must do one of the following:

- Enter Debug state.
- Pend the debug event.
- Generate a debug exception.
- Ignore the debug event.

This behavior depends on both:

- Whether halting is allowed by the current state of the debug authentication interface. See *Halting allowed and halting prohibited*.
- The type of debug event and the programming of the debug control registers.
  - See *Halting debug events* for all Halting debug events.
  - See *Breakpoint and Watchpoint debug events* on page H2-4696 for Breakpoint and Watchpoint debug events.

See also *Other debug exceptions* on page H2-4697.

This means that behavior can be CONSTRAINED UNPREDICTABLE if the conditions change. See *Synchronization and Halting debug events* on page H3-4754.

Summary of debug events and possible outcomes on page H3-4734 summarizes the possible outcomes of each type of debug event.

H2.2.1 Halting allowed and halting prohibited

Halting can be either allowed or prohibited:

- Halting is always prohibited in Debug state.
- Halting is always prohibited when `DoubleLockStatus()` == TRUE.
  - This means that OS Double Lock is locked.
- Halting is also controlled by the IMPLEMENTATION DEFINED authentication interface, and is prohibited when either:
  - The PE is in Non-secure state and `ExternalInvasiveDebugEnabled()` == FALSE.
  - The PE is in Secure state and `ExternalSecureInvasiveDebugEnabled()` == FALSE.

  Note

  See Appendix K2 *Recommended External Debug Interface* for more information on these functions.
- Otherwise, halting is allowed.

See *Pseudocode description of Halting on debug events* on page H2-4701.

H2.2.2 Halting debug events

When a Halting debug event is generated, it causes entry to Debug state if both:

- Halting is allowed. See *Halting allowed and halting prohibited*.
- The Halting debug event is either:
  - A Halt Instruction debug event when Halting debug is enabled. This means that EDSCR.HDE == 1.
  - Not a Halt Instruction debug event.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Note

— An Halt Instruction debug event is the only Halting debug event that relies on EDSCR.HDE == 1. This is to prevent malicious code from causing an entry Debug state. EDSCR.HDE == 0 on a Cold reset.

— Halting on Breakpoint and Watchpoint Software debug events is also controlled by EDSCR.HDE. See *Breakpoint and Watchpoint debug events*.

— EDSCR.HDE can be written by software when the OS Lock is locked. Privileged code can use SDCR.TDOSA and HDCR.TDOSA to trap writes to these registers.

If a Halting debug event does not generate entry to Debug state because the conditions listed in this section do not hold, then:

- If the Halting debug event is a Halt Instruction debug event, it generates an Undefined Instruction exception.
- If the Halting debug event is an Exception Catch debug event or a Software Access debug event, it is ignored.
- In all other cases the Halting debug event is pended, meaning that:
  - The pending Halting debug event is recorded in EDESR.
  - The pending Halting debug event is taken when halting is allowed. See *Pending Halting debug events* on page H3-4754.

Pending Halting debug events are discarded by a Cold reset. The debugger can also force a pending event to be dropped by writing to EDESR. *Summary of actions from debug events* on page H2-4700 summarizes the possible outcome for each type of Debug event.

Note

Halting debug events never generate Debug exceptions.

H2.2.3 Breakpoint and Watchpoint debug events

A breakpoint or watchpoint generates an entry to Debug state if all of the following conditions hold:

- Halting debug is enabled, that is EDSCR.HDE == 1.
- Halting is allowed. See *Halting allowed and halting prohibited* on page H2-4695.
- The OS Lock is unlocked, that is OSLSR.OSLK == 0.

The Address Mismatch breakpoint type is reserved when all of these conditions are met.

MDSCR_EL1.MDE or DBGDSCRext.MDBGen is ignored when determining whether to enter Debug state. A breakpoint or watchpoint that generates entry to Debug state is a Breakpoint or Watchpoint debug event and does not generate a debug exception.

A breakpoint or watchpoint that does not generate an entry to Debug state either:

- Generates a Breakpoint or Watchpoint exception.
- Is ignored.

Note

EDSCR.HDE is ignored when determining whether to generate a debug exception. The debug exception is suppressed only if the PE enters Debug state. This means that the use of Halting debug mode in Non-secure state does not affect the Exception model in Secure state.

See Chapter D2 *AArch64 Self-hosted Debug*, Chapter G2 *AArch32 Self-hosted Debug*, and the Note in *Other debug exceptions* on page H2-4697.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H2.2.4 Other debug exceptions

The following events never generate entry to Debug state:

- Software Breakpoint Instruction exceptions.
- Software Step exceptions.
- Vector Catch exceptions.

The behavior of these events is unchanged when Halting debug mode is enabled, that is when EDSCR.HDE == 1. This means that these events can do one of the following:

- They can generate a debug exception.
- They can be ignored.

For additional information, see Chapter D2 *AArch64 Self-hosted Debug* and Chapter G2 *AArch32 Self-hosted Debug*.

H2.2.5 Debug state entry and debug event prioritization

The architecture does not define when asynchronous Halting debug events are taken, and therefore the prioritization of asynchronous debug events is IMPLEMENTATION DEFINED.

Synchronous Halting debug events do have a priority order.

The following are synchronous Halting debug events:

- Halting Step debug event.
- Halt Instruction debug event.
- Exception Catch debug event.
- Software Access debug event.
- Reset Catch debug event.

Each of these synchronous Halting debug events is treated as a synchronous exception generated by an instruction, or by the taking of an exception or reset. That is, the synchronous Halting debug event must be taken before any subsequent instructions are executed. Reset Catch debug events must be taken before the PE executes the instruction at the reset vector.

Note

Reset Catch and Exception Catch debug events can be generated asynchronously, because they can result from an asynchronous exception. However, if halting is allowed after the asynchronous exception has been processed, the Reset Catch or Exception Catch debug event is taken synchronously.

The Halting Step debug event is generated by the instruction after the stepped instruction. Therefore, if the stepped instruction generates any other synchronous exceptions or debug events, these are taken first.

OS Unlock Catch debug events are always pended and taken asynchronously.

Halting Step debug events and Reset Catch debug events might be pended and taken asynchronously at a later time.

The following list shows how the events are prioritized, with -2 being the highest priority.

Note

The priority numbering is the same as the numbering for AArch64 synchronous exception priorities listed in *Synchronous exception types, routing and priorities* on page D1-1477. The Debug events in this section with a negative priority are a higher priority than any synchronous exception. The debug events with fractional priorities have a priority between two or more exceptions.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

The priority for synchronous debug events is as follows:

-2 Reset Catch debug event. See *Reset Catch debug events* on page H3-4752.

This debug event has a higher priority than the synchronous exceptions listed in *Synchronous exception types, routing and priorities* on page D1-1477.

-1 Exception Catch debug event. See *Exception Catch debug event* on page H3-4747.

This debug event can be assigned one of two priorities. When it has a priority of -1, it has a higher priority than the synchronous exceptions listed in the Exception model. See *Exception Catch debug event* on page H3-4747.

0 Halting Step debug event. See *Halting Step debug events* on page H3-4736.

This debug event has a higher priority than the synchronous exceptions listed in the Exception model.

1 Software Step debug event. See *Software Step exceptions* on page D2-1598.

1.5 Exception Catch debug event. See *Exception Catch debug event* on page H3-4747.

This debug event can be assigned one of two priorities, -1 or 1.5. See *Exception Catch debug event* on page H3-4747.

2 - 3 These events are not debug events.

4 Breakpoint exception or debug event or Address Matching Vector Catch exception. See *Breakpoint exceptions* on page D2-1569, and *Vector Catch exceptions* on page G2-3829.

These two debug events have the same priority.

5 - 13 These events are not debug events.

14 Halt Instruction debug event. See *Halt Instruction debug event* on page H3-4746.

15 - 19 These events are not debug events.

19.5 Software Access debug event. See *Software Access debug event* on page H3-4753.

20 - 21 These events are not debug events.

22 Watchpoint exception or debug event. See *Watchpoint exceptions* on page D2-1584 for exceptions taken from AArch64 state, or *Watchpoint exceptions* on page G2-3816 for exceptions taken from AArch32 state.

23 This event is not a debug event.

For Reset Catch debug events and Halting Step debug events the priorities listed in this section only apply when halting is allowed at the time the event is generated. This means that the event is taken synchronously and not pended.

The prioritization of asynchronous Halting debug events, including pending Halting debug events taken asynchronously, is IMPLEMENTATION DEFINED. See *Taking Halting debug events asynchronously* on page H3-4755.

For more information on the prioritization of exceptions see *Synchronous exception types, routing and priorities* on page D1-1477.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Breakpoint debug events and Vector Catch exception

An Address Matching Vector Catch exception has the same priority as a Breakpoint debug event. See *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478.

The prioritization of these events is unchanged even if the breakpoint generates entry to Debug state instead of a Breakpoint exception. This means that if a single instruction generates both an Address Matching Vector Catch exception and a Breakpoint debug event, there is a CONSTRAINED UNPREDICTABLE choice of:

- The PE entering Debug state due to the Breakpoint debug event.
- A Vector Catch exception.

This only applies if all of the following are true:

- Halting debug is enabled.
- Halting is allowed.
- The OS Lock is unlocked.

An Exception Trapping Vector Catch exception must be generated immediately following the exception that generated it. This means that it does not appear in the priority table.

H2.2.6 Forcing entry to Debug state

Entry to Debug state is normally precise, meaning that the PE cannot enter Debug state if it can neither complete nor abandon all currently executing instructions and leave the PE in a precise state.

A debugger can write a value of 1 to EDRCR.CBRRQ to allow imprecise entry to Debug state. An External Debug Request debug event must be pending before writing 1 to this bit. Support for this feature is OPTIONAL and it is IMPLEMENTATION DEFINED when it is effective at forcing entry to Debug state.

The PE ignores writes to this bit if either:

- External debugging is not enabled, meaning `ExternalInvasiveDebugEnabled()` == FALSE.
- Secure external debugging is not enabled, meaning `ExternalSecureInvasiveDebugEnabled()` == FALSE, and either:
  - EL3 is not implemented and the implemented Security state is Secure state.
  - EL3 is implemented.

Example H2-1 shows how entry to Debug state can be forced.

Example H2-1 Forcing entry to Debug state

The debugger pends an External Debug Request debug event through the CTI to halt a program that has stopped responding. However, the memory system is not responding and a memory access instruction cannot complete. This means that Debug state cannot be entered precisely. The debugger writes a value of 1 to EDRCR.CBRRQ. The PE cancels all outstanding memory accesses and enters Debug state. As some instructions might not have completed correctly, entry to Debug state is imprecise.

When Debug state is entered imprecisely, all memory access instructions executed through the ITR have CONSTRAINED UNPREDICTABLE behavior. The value of all registers is UNKNOWN, but might be useful for diagnostic purposes.

Non-Confidential - Beta

H2.2.7 Summary of actions from debug events

Table H2-1 shows the Software and Halting debug events. In Table H2-1 the columns have the following meaning:

Debug event type

This means the type of debug event where:

Other software Means one of:

- *Software Step exceptions* on page D2-1598.
- *Software Breakpoint Instruction exceptions* on page D2-1567.
- *Vector Catch exceptions* on page D2-1597 for AArch64 state or *Vector Catch exceptions* on page G2-3829 for AArch32 state.

Other Halting Means one of the following:

- *Halting Step debug events* on page H3-4736.
- *External Debug Request debug event* on page H3-4750.
- *Reset Catch debug events* on page H3-4752.
- *OS Unlock Catch debug event* on page H3-4751.

Other debug events are referred to explicitly.

Authentication

This means halting is allowed by the IMPLEMENTATION DEFINED external authentication interface. It is the result of one of the following pseudocode functions:

In Secure state `ExternalSecureInvasiveDebugEnabled()`.

In Non-secure state `ExternalInvasiveDebugEnabled()`.

DLK This indicates whether the OS Double Lock is locked, `DoubleLockStatus()` == TRUE.

OSLK This is the value of OSLSR.OSLK. It indicates whether the OS Lock is locked.

HDE This is the value of EDSCR.HDE. It indicates whether Halting debug is enabled.

The letter X in Table H2-1 indicates that the value can be either 0 or 1.

Table H2-1 Debug authentication for external debug

Debug event type	Authentication	DLK	OSLK	HDE	Behavior
Other software	X	X	X	X	Handled by the Exception model
Breakpoint or Watchpoint debug event	X	TRUE	X	X	Handled by the Exception model (ignored)
	X	FALSE	1	X	Handled by the Exception model (ignored)
	FALSE	FALSE	0	X	Handled by the Exception model
	TRUE	FALSE	0	0	Handled by the Exception model
	TRUE	FALSE	0	1	Entry to Debug state
Halt Instruction debug event	FALSE	X	X	X	UNDEFINED
	TRUE	TRUE	X	X	UNDEFINED
	TRUE	FALSE	X	0	UNDEFINED
	TRUE	FALSE	X	1	Entry to Debug state

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Table H2-1 Debug authentication for external debug (continued)

Debug event type	Authentication	DLK	OSLK	HDE	Behavior
Exception Catch debug event	FALSE	X	X	X	Ignored
	TRUE	TRUE	X	X	Ignored
	TRUE	FALSE	X	X	Entry to Debug state
Software Access debug event	FALSE	X	X	X	Ignored
	TRUE	TRUE	X	X	Ignored
	TRUE	FALSE	1	X	Ignored
	TRUE	FALSE	0	X	Entry to Debug state
Other Halting	FALSE	X	X	X	Debug event is pended
	TRUE	TRUE	X	X	Debug event is pended
	TRUE	FALSE	X	X	Entry to Debug state

H2.2.8 Pseudocode description of Halting on debug events

The `Halted()`, `Restarting()`, `HaltingAllowed()`, and `HaltOnBreakpointOrWatchpoint()` functions are described in the ARMv8 pseudocode.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H2.3 Entering Debug state

On entry to Debug state the preferred restart address and PSTATE are saved in DLR and DSPSR. The PE remains in the mode and security state from which it entered Debug state.

If EDRCR.CBRRQ has a value of 0, entry to Debug state is precise. If EDRCR.CBRRQ has a value of 1, then imprecise entry to Debug state is permitted.

If a Watchpoint debug event causes an entry to Debug state, the address of the access that generated the Watchpoint debug event is recorded in EDWAR. See *Determining the memory location that caused a Watchpoint exception* on page D2-1591 for an exception taken from AArch64 state, or *Determining the memory location that caused a Watchpoint exception* on page G2-3823 for an exception taken from AArch32 state.

Other than the effect on PSTATE and EDSCR, entry to Debug state is not a *Context synchronization operation*. The effects of entry to Debug state on PSTATE and EDSCR are synchronized.

H2.3.1 Entering Debug state from AArch32 state

When entering Debug state from AArch32 state, the PE remains in AArch32 state. In AArch32 Debug state the PE executes T32 instructions, regardless of the value of PSTATE.T before entering Debug state.

To allow the debugger to determine the state of the PE, the current Execution state for all four Exception levels can be read from EDSCR.RW, and the current Exception level can be read from EDSCR.EL.

The current endianness state, PSTATE.E, is unchanged on entry to Debug state.

Note

- If EL1 is using AArch32 state, the current endianness state can differ from that indicated by SCTLR.EE.
- If EL2 is using AArch32 state, the current endianness state can differ from that indicated by HSCTLR.EE.
- On entry to Debug state from AArch32 state, PSTATE.SS is copied to DSPSR.SS, even though the PE remains in AArch32 state.

See also *Effect of entering Debug state on PSTATE* on page H2-4703.

H2.3.2 Effect of entering Debug state on DLR and DSPSR

DLR is set to the preferred restart address for the debug event, that depends on the event type. The value of PSTATE is saved in DSPSR. For entry to Debug state from AArch32 state, the values saved in DSPSR.IT are always correct for the preferred restart address.

For synchronous Halting debug events, the preferred restart address is the address of the instruction that generated the debug event.

For asynchronous Halting debug events, including pending Halting debug events taken asynchronously, the preferred restart address is the address of the first instruction that must be executed on exit from Debug state.

This means that:

- For Breakpoint and Watchpoint debug events, the preferred restart address is the same as the preferred return address for a debug exception, as described in Chapter D2 *AArch64 Self-hosted Debug* and Chapter G2 *AArch32 Self-hosted Debug*.
- For Halt Instruction debug events DLR is set to the address of the `HLT` instruction and DSPSR.IT is correct for the `HLT` instruction.
- For Software Access debug events, DLR is set to the address of the accessing instruction and DSPSR.IT is correct for this instruction.
- For Halting Step debug events taken synchronously, DLR and DSPSR are set as the ELR and SPSR would be set for a Software Step exception. This is usually the address of, and PSTATE for, the instruction after the one that was stepped.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- For Exception Catch debug events:
  - If the debug event is generated on taking an exception to a trapped Exception level, the DLR is set to the address of the exception vector the PE would have started fetching from. This is UNKNOWN if the VBAR for the Exception level has never been initialized. The DSPSR records the value of PSTATE after taking the exception. The exception catch occurs after the SPSR and the Link register are set, and the debugger can use these registers to determine where in the application program the exception occurred.

    Note

    Depending on the target Exception level and Execution state for the exception, the Link register is one of ELR_EL1, ELR_EL2, ELR_EL3, ELR_hyp, or LR (R14).

  - If the debug event is generated on an exception return to a trapped Exception level, the DLR is set to the target address of the exception return and the DSPSR records the value of PSTATE after the exception return.
- Reset Catch debug events taken synchronously behave like Exception Catch debug events.
- For Reset Catch debug events and Exception Catch debug events generated on reset to a trapped Exception level, the DLR is set to is set to the reset address and the DSPSR records the reset value of PSTATE.
- For pending Halting debug events and External Debug Request debug events, DLR is set to the address of the first instruction that must be executed on exit from Debug state and DSPSR.IT is correct for this instruction. See *Pending Halting debug events* on page H3-4754.

Normally DLR is aligned according to the instruction set state indicated in DSPSR. However, a debug event might be taken at a point where the PC is not aligned.

H2.3.3 Effect of Debug state entry on System registers, the Event register, and exclusive monitors

Entering Debug state has no effect on System registers other than DLR and DSPSR. In particular, ESRs, FARs, and FSRs are not updated on entering Debug state. SCR is unchanged, even when entering Debug state from EL3.

Entering Debug state has no architecturally-defined effect on the Event Register and exclusive monitors.

Note

Entry to Debug state might set the Event Register or clear the exclusive monitors, or both. However, this is not a requirement, and debuggers must not rely on any implementation specific behavior.

Unless otherwise described in this reference manual, instructions executed in Debug state have their architecturally-defined effects on the System registers, the Event register, and exclusive monitors.

H2.3.4 Effect of entering Debug state on PSTATE

The effect of an entry to Debug state on PSTATE is described in *Entering Debug state* on page H2-4702 and *Entering Debug state from AArch32 state* on page H2-4702.

PSTATE.{E, M, nRW, EL, SP} are unchanged on entry to Debug state.

PSTATE.IL is cleared to 0 on entry to Debug state, after being saved in DSPSR_EL0.

The other PSTATE fields are ignored and not observable in Debug state:

- PSTATE.{N, Z, C, V, Q, GE} are unchanged.
- PSTATE.{IT, T, SS, D, A, I, F} are set to UNKNOWN values, after being saved in DSPSR_EL0.

For more information see *Process state (PSTATE) in Debug state* on page H2-4705.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H2.3.5 Entering Debug state during loads and stores

The PE can enter Debug state during instructions that perform a sequence of memory accesses, as opposed to a single single-copy atomic access, because of a Watchpoint debug event. The effect of entering Debug state on such an instruction is the same as taking a Data Abort exception during such an instruction.

In addition, when executing in AArch64 state, the PE can enter Debug state during instructions that perform a sequence of memory accesses because of an External Debug Request debug event. The effect of entering Debug state on such an instruction is the same as taking an interrupt exception during such an instruction.

This applies to all memory types.

H2.3.6 Entering Debug state and Software Step

When Software Step is active, a debug event that causes entry to Debug state behaves like an exception taken to an Exception level above the debug target Exception level. That is:

- If the instruction that is stepped generates a synchronous debug event that causes entry to Debug state, or an asynchronous debug event is taken before the step completes, the PE enters Debug state with DSPSR.SS set to 1.
- A pending Halting debug event or an asynchronous debug event can be taken after the step has completed. In this case the PE enters Debug state with DSPSR.SS set to 0.

In addition:

- If the instruction that is stepped generates an exception trapped by an Exception Catch debug event, the PE enters Debug state at the exception vector with DSPSR.SS set to 0. This is because PSTATE.SS is set to 0 by taking the exception.
- If the PE is reset, PSTATE.SS is reset to 0. If the following debug events are enabled, the PE enters Debug state with DSPSR.SS set to 0:
  - Reset Catch debug event at the reset Exception level.
  - Exception Catch debug event at the reset Exception level.
  - Halting Step debug event.
- If Halting Step is also active, then Halting Step and Software Step operate in parallel and can both become active-pending. In this case Halting step has a higher priority than Software step. This means that the PE enters Debug state and DSPSR.SS is set to 0.

H2.3.7 Pseudocode description of entering Debug state

The `DebugHalt` constants are described in *shared/debug/halting/DebugHalt* on page J1-5217 in the ARMv8 pseudocode. The `UpdateEDSCRFields()` and `Halt()` functions are described in Chapter J1 *ARMv8 Pseudocode*.

H2.4 Behavior in Debug state

Instructions are executed in Debug state from the Instruction Transfer Register, ITR. The debugger controls which instructions are executed in Debug state by writing the instructions to the External Debug Instruction Transfer register, EDITR. The Execution state of the PE determines which instruction set is executed:

- If the PE is in AArch64 state it executes A64 instructions.
- If the PE is in AArch32 state it executes T32 instructions.

The PE does not execute A32 instructions in Debug state.

Some instructions are available only in Debug state. See *Debug state instructions, DCPS, DRPS, MRS, MSR* on page H2-4721. In Non-debug state these instructions are UNDEFINED.

The following sections describe behavior in Debug state:

- *Process state (PSTATE) in Debug state*.
- *Executing instructions in Debug state*.
- *Decode tables* on page H2-4716.
- *Security in Debug state* on page H2-4719.
- *Privilege in Debug state* on page H2-4720.
- *Debug state instructions, DCPS, DRPS, MRS, MSR* on page H2-4721.
- *Exceptions in Debug state* on page H2-4724.
- *Accessing registers in Debug state* on page H2-4726.
- *Accessing memory in Debug state* on page H2-4729.

This section specifies the CONSTRAINED UNPREDICTABLE behaviors that apply in Debug state, but see *Setting the value of EDECR.SS to 1 when not in Debug state* on page K1-5380 for a change in Non-debug state that causes CONSTRAINED UNPREDICTABLE behavior in Debug state.

H2.4.1 Process state (PSTATE) in Debug state

PSTATE.{N, Z, C, V, Q, GE, IT, T, SS, D, A, I, F} are all ignored in Debug state:

- There are no conditional instructions in Debug state.
- In AArch32 state, the PE only executes T32 instructions and PSTATE.IT is ignored.
- Asynchronous exceptions and debug events are ignored.
- Software step is inactive.

Instructions executed in Debug state indirectly read PSTATE.{IL, E, M, nRW, EL, SP} as they would in Non-debug state.

H2.4.2 Executing instructions in Debug state

The instructions executed in Debug state must be either A64 instructions or T32 instructions, depending on the current Execution state.

Each instruction falls into one of the following groups:

- Debug state instructions. These are instructions that are changed in Debug state. See *A64 instructions that are changed in Debug state* on page H2-4706 and *T32 instructions that are changed in Debug state* on page H2-4710.
- Instructions that are unchanged in Debug state. See *A64 instructions that are unchanged in Debug state* on page H2-4706 and *T32 instructions that are unchanged in Debug state* on page H2-4711.
- Instructions that are UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Debug state. See *A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state* on page H2-4708 and *T32 instructions that are CONSTRAINED UNPREDICTABLE in Debug state* on page H2-4713.

All T32 instructions are treated as unconditional, regardless of PSTATE.IT. See *Process state (PSTATE) in Debug state*.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

If EDSCR.SDD == 1 then an instruction executed in Non-secure state cannot cause entry into Secure state. See *Security in Debug state* on page H2-4719

Executing A64 instructions in Debug state

The following sections describe the behavior of the A64 instructions in Debug state:

- *A64 instructions that are changed in Debug state*.
- *A64 instructions that are unchanged in Debug state*.
- *A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state* on page H2-4708.

A64 instructions that are changed in Debug state

The following A64 instructions are defined in Debug state, but are UNDEFINED in Non-debug state:

- DCPS

  Note

  DCPS can be UNDEFINED in certain conditions in Debug state. See *DCPS* on page H2-4721.

- DRPS
- MRS (DLR_EL0), MRS (DSPSR_EL0), MSR (DLR_EL0), MSR (DSPSR_EL0)

For more information see *Debug state instructions, DCPS, DRPS, MRS, MSR* on page H2-4721.

A64 instructions that are unchanged in Debug state

The following list shows the instructions that are unchanged in Debug state:

Any instruction that is UNDEFINED in Non-debug state

This list of instructions excludes:

- Any instruction listed in *A64 instructions that are changed in Debug state*.
- Any instruction listed in *A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state* on page H2-4708 that is UNDEFINED because an enable or disable bit is not RES0 or RES1

Instructions that move System or Special-purpose registers to or from a general-purpose register

This list of instructions:

- Includes the instructions to transfer a general-purpose register to or from the DTR, which can be executed at any Exception level.
- Excludes PSTATE access instructions.

These instructions are:

- MRS <special_reg>, MSR <special_reg>

  Note

  This does not include NZCV, DAIF, DAIFSet, DAIFClr, SPSel, and CurrentEL.

- MRS <system_reg>, MSR <system_reg>

Floating-point moves between a SIMD&FP register and a general-purpose register

These instructions are:

- FMOV (between a general-purpose register and a single-precision register).
- FMOV (between a general-purpose register and a double-precision register).
- FMOV (between a general-purpose register and a SIMD element).

SIMD moves between a SIMD&FP register and a general-purpose register

These instructions are:

- INS (from a general-purpose register to a SIMD element).

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- `UMOV` (from a SIMD element to a general-purpose register).

Barriers These instructions are:

- `ISB`.
- `DSB`.
- `DMB`.

Memory access instructions at various access sizes

The following constraints apply:

- General purpose-registers only.
- One of the following addressing modes:
  - Unscaled (9-bit signed) immediate offset.
  - Immediate (9-bit signed) post-indexed.
  - Immediate (9-bit signed) pre-indexed.
  - Unprivileged (9-bit signed).
- Not literal.
- One of the following types:
  - (Single) register.
  - Exclusive.
  - Exclusive pair.
  - Acquire/Release.
  - Acquire/Release Exclusive.
  - Acquire/Release Exclusive pair.
- 32-bit and 64-bit target register variants.

These instructions are:

- `LDR`, `LDRB`, `LDRH`, `LDRSB`, `LDRSH`, `LDRSW` (immediate, not literal).
- `LDUR`, `LDURB`, `LDURH`, `LDURSB`, `LDURSH`, `LDURSW` (immediate).
- `LDTR`, `LDTRB`, `LDTRH`, `LDTRSB`, `LDTRSH`, `LDTRSW` (immediate).
- `LDAR`, `LDARB`, `LDARH`, `LDXR`, `LDXRB`, `LDXRH`, `LDAXR`, `LDAXRB`, `LDAXRH`.
- `LDXP`, `LDAXP`.
- `STR`, `STRB`, `STRH` (immediate).
- `STUR`, `STURB`, `STURH` (immediate).
- `STTR`,`STTRB`, `STTRH` (immediate).
- `STLR`, `STLRB`, `STLRH`, `STXR`, `STXRB`, `STXRH`, `STLXR`, `STLXRB`, `STLXRH`.
- `STXP`, `STLXP`.

Move immediate to general-purpose register

These instructions are:

- `MOVZ`, `MOVN`, `MOVK` (immediate).
- `MOV` (between a general-purpose register and the stack pointer).

Cache maintenance, Send Event, NOP, and Clear Exclusive

These instructions are:

- `IC`.
- `DC`.
- `TLBI`.
- `AT`.
- `SEV`, `SEVL`.
- `NOP` (no operation hint).
- `CLREX`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state

This subsection describes all instruction not listed in either:

- *A64 instructions that are changed in Debug state* on page H2-4706.
- *A64 instructions that are unchanged in Debug state* on page H2-4706.

These instructions are CONSTRAINED UNPREDICTABLE in Debug state. In general, the permissible behaviors are:

- The instruction generates an Undefined Instruction exception.
- The instruction executes as a `NOP`.
- If the instruction reads the PC or PSTATE, it uses an UNKNOWN value.
- If the instruction modifies the PC or PSTATE, other than by advancing the PC to the sequentially next instruction, it sets DLR_EL0 and DSPSR_EL0 to UNKNOWN values.
- If the instruction is similar to a Debug state instruction, it executes as that Debug state instruction.
- The instruction has the same behavior as in Non-debug state.

The following list shows the permissible behaviors for A64 instruction in Debug state. An instruction might appear multiple times in the list, in which case the choice of permissible behaviors is any of those listed. An example of this is `CCMP`.

Exception-generating instructions

These instructions are:

- `SVC`.
- `HVC`.
- `SMC`.
- `BRK`.
- `HLT`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- `SVC` behaves as `DCPS1`.
- `HVC` behaves as `DCPS2`.
- `SMC` behaves as `DCPS3`.
- They generate the exception that the instruction would generate in Non-debug state. The exception is taken as described in *Exceptions in Debug state* on page H2-4724

Note

`SMC` must not generate a Secure Monitor Call exception from Non-secure state if EDSCR.SDD is set to 1.

Instructions that explicitly write to the PC (branches)

These instructions are:

- `B`, `B.cond`, `BL`, `BLR`, `BR`, `CBZ`, `CBNZ`, `RET`, `TBZ`, `TBNZ`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state without branching and set DSPSR_EL0 and DLR_EL0 to UNKNOWN values.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Exception return and related instructions

These instructions are:

- `ERET`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They execute as in Non-debug state without branching. They set DSPSR_EL0 and DLR_EL0 to UNKNOWN values, and either:
  - Execute as `DRPS` instead of performing an exception return, using UNKNOWN SPSR values.
  - Not change the Exception level.

Instructions that explicitly modify PSTATE, other than `DCPS` and `DRPS`

These instructions are:

- `MSR DAIFSet` (immediate), `MSR DAIFClr` (immediate), `MSR SPSel` (immediate).
- `MSR NZCV` (register), `MSR DAIF` (register), `MSR SPSel` (register).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They execute as in Non-debug state, setting DSPSR_EL0 and DLR_EL0 to UNKNOWN values.

Instructions that suspend execution

These instructions are:

- `WFE`, `WFI`

These instructions behave in one of the following ways:

- Are UNDEFINED.
- Execute as a `NOP`.
- Generate a synchronous exception if the corresponding instruction would be trapped in Non-debug state. See *Configurable instruction enables and disables, and trap controls* on page D1-1491.

Note

This means that these instructions must not suspend execution.

Instructions that read the PC

These instructions are:

- `LDR` (literal), `LDRSW` (literal).
- `ADR`, `ADRP`.
- `PRFM` (literal).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They execute as in Non-debug state, using an UNKNOWN value for the PC operand.

Instructions that read the PSTATE.{N, Z, C, V} or other PSTATE fields

These instructions are:

- `CSEL`, `CSINC`, `CSINV`, `CSNEG`, `CCMN`, `CCMP`, `FCSEL`, `FCCMP`, `FCCMPE`.
- `ADC`, `ADCS`,`SBC`, `SBCS`.
- `MRS NZCV`, `MRS DAIF`, `MRS SPSel`, `MRS CurrentEL`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state:
  - For the conditional operations and those using the PSTATE.C flag as an input, these instructions use an UNKNOWN value for the condition flag.
  - For the MRS instruction, they return an UNKNOWN value.

Instructions that explicitly modify the PSTATE. {N, Z, C, V, Q, GE}

These instructions are:

- ADDS, SUBS, ADCS, SBCS, ANDS, BICS, CCMN, CCMP.
- FCMP, FCMPE, FCCMP, FCCMPE.
- MSR NZCV (register).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state, setting DSPSR_EL0 and DLR_EL0 to UNKNOWN values.

All other instructions

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They have the same behavior as in Non-debug state.

Note

This includes instructions defined as UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Non-debug state. These instructions are UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Debug state.

Executing T32 instructions in Debug state

The following sections describe the behavior of the T32 instructions in Debug state:

- *T32 instructions that are changed in Debug state*.
- *T32 instructions that are unchanged in Debug state* on page H2-4711.
- *T32 instructions that are CONSTRAINED UNPREDICTABLE in Debug state* on page H2-4713.

T32 instructions that are changed in Debug state

The following T32 instructions are defined in Debug state, but are UNDEFINED in Non-debug state:

- DCPS

  Note

  DCPS can be UNDEFINED in certain conditions in Debug state. See *DCPS* on page H2-4721.

- MRC p15,3,<Rt>,c4,c5,0 (DSPSR)
- MCR p15,3,<Rt>,c4,c5,0 (DSPSR)
- MRC p15,3,<Rt>,c4,c5,1 (DLR)
- MCR p15,3,<Rt>,c4,c5,1 (DLR)

In addition, ERET is executed as DRPS in Debug state.

For more information see *Debug state instructions, DCPS, DRPS, MRS, MSR* on page H2-4721.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

T32 instructions that are unchanged in Debug state

The following list shows the instructions that are unchanged in Debug state. Any T32 instruction that uses the PC or APSR.{N, Z, C, V} as the source or destination register is not included in the list. Moreover, the list only includes the 32-bit T32 encodings.

Any instruction that is UNDEFINED in Non-debug state

The list of instructions:

- Excludes any instruction listed in *T32 instructions that are changed in Debug state* on page H2-4710.
- Excludes any instruction listed in *T32 instructions that are CONSTRAINED UNPREDICTABLE in Debug state* on page H2-4713 that is UNDEFINED because an enable or disable bit is not RES0 or RES1

Instructions that move System or Special-purpose registers to or from a general-purpose register

The list of instructions:

- Includes the instructions to transfer a general-purpose register to or from the DTR, which can be executed at any Exception level.
- Excludes APSR and CPSR access instructions.
- Excludes instructions for accessing banked registers for the current mode.

These instructions are:

- `MRS <spec_reg>_<mode>`, `MSR <spec_reg>_<mode>`.

  Note

  This does not apply to cases which are UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Non-debug state in the current mode.

- `MRC <system_reg>`, `MCR <system_reg>`

  Note

  This includes all allocated CP15 and CP14 System registers, other than an `MRC` move to APSR_nzcv.

- `MRS SPSR`, `MSR SPSR`
- `VMRS <vfp_system_reg>`, `VMSR <vfp_system_reg>`

  Note

  This includes all allocated Advanced SIMD and floating-point System registers, other than an a `VMRS` move to APSR_nzcv.

Floating-point moves between a SIMD&FP register and a general-purpose register

These instructions are:

- `VMOV` (between a general-purpose register and a single-precision register).
- `VMOV` (between a general-purpose register and a doubleword floating-point register).

SIMD moves between a SIMD&FP register and a general-purpose register

These instructions are:

- `VMOV` (between a general-purpose register and a scalar).

Barriers These instructions are:

- `ISB`.
- `DSB`.
- `DMB`.

Memory access instructions at various access sizes

The following constraints apply:

- General purpose-registers only.
- One of the following addressing modes:
  - Immediate (8-bit or 12-bit) offset.
  - Immediate (8-bit) post-indexed.
  - Immediate (8-bit) pre-indexed.
  - Unprivileged (8-bit).
- Not literal.
- One of the following types:
  - (Single) register.
  - Dual.
  - Exclusive.
  - Exclusive doubleword.
  - Acquire/Release.
  - Acquire/Release Exclusive.
  - Acquire/Release Exclusive doubleword.

These instructions are:

- `LDR.W`, `LDRB.W`, `LDRH.W`, `LDRD`, `LDRSB.W`, `LDRSH.W` (immediate, not literal).
- `LDRT`, `LDRBT`, `LDRHT`, `LDRSBT`, `LDRSHT` (immediate).
- `LDREX`, `LDREXB`, `LDREXH`, `LDA`, `LDAB`, `LDAH`, `LDAEX`, `LDAEXB`, `LDAEXH`.
- `LDREXD`, `LDAEXD`.
- `STR.W`, `STRB.W`, `STRH.W`, `STRD` (immediate).
- `STRT`, `STRBT`, `STRHT` (immediate).
- `STREX`, `STREXB`, `STREXH`, `STL`, `STLB`, `STLH`, `STLEX`, `STLEXB`, `STLEXH`.
- `STREXD`, `STLEXD`.

Move to general-purpose register

These instructions are:

- `MOVW`, `MOVT` (immediate).

Cache maintenance, Send Event, `NOP`, and Clear Exclusive

These instructions are:

- `ICIALLU`, `ICIALLUIS`, `ICIMVAU` (CP15 operations).
- `DCCIMVAC`, `DCCISW`, `DCCMVAC`, `DCCMVAU`, `DCCSW`, `DCIMVAC`, `DCISW` (CP15 operations).
- `TLBIALL`, `TLBIALLH`, `TLBIALLHIS`, `TLBIALLIS`, `TLBIALLNSNH`, `TLBIALLNSNHIS`, `TLBIASID`, `TLBIASIDIS`, `TLBIIPAS2`, `TLBIIPAS2IS`, `TLBIIPAS2L`, `TLBIIPAS2LIS`, `TLBIMVA`, `TLBIMVAA`, `TLBIMVAAIS`, `TLBIMVAAL`, `TLBIMVAALIS`, `TLBIMVAH`, `TLBIMVAHIS`, `TLBIMVAIS`, `TLBIMVAL`, `TLBIMVALH`, `TLBIMVALHIS`, `TALBIMVALIS` (CP15 operations).
- `ATS12NSOPR`, `ATS12NSOPW`, `ATS12NSOUR`, `ATS12NSOUW`, `ATS1CPR`, `ATS1CPW`, `ATS1CUR`, `ATS1CUW`, `ATS1HR`, `ATS1HW` (CP15 operations).
- `BPIALL`, `BPIALLIS`, `BPIMVA` (CP15 operations).
- `SEV.W`, `SEVL.W`.
- `NOP.W` (no operation hint).
- `CLREX`.

T32 instructions that are CONSTRAINED UNPREDICTABLE in Debug state

This subsection describes all instruction not listed in either:

- *T32 instructions that are changed in Debug state* on page H2-4710.
- *T32 instructions that are unchanged in Debug state* on page H2-4711.

These instructions are CONSTRAINED UNPREDICTABLE in Debug state. In general, the permissible behaviors are:

- The instruction generates an Undefined Instruction exception.
- The instruction executes as a `NOP`.
- If the instruction reads the PC or PSTATE, it uses an UNKNOWN value.
- If the instruction modifies the PC or PSTATE, other than by advancing the PC to the sequentially next instruction, it sets DLR and DSPSR to UNKNOWN values.
- If the instruction is similar to a Debug state instruction, it executes as that Debug state instruction.
- The instruction has the same behavior as in Non-debug state.

The following list shows the permissible behaviors for T32 instruction in Debug state. An instruction might appear multiple times in the list, in which case the choice of permissible behaviors is any of those listed.

Exception-generating instructions

These instructions are:

- `SVC`.
- `HVC`.
- `SMC`.
- `UDF`.
- `BKPT`.
- `HLT`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- `SVC` behaves as `DCPS1`.
- `HVC` behaves as `DCPS2`.
- `SMC` behaves as `DCPS3`.
- They generate the exception the instruction would generate in Non-debug state. The exception is taken as described in *Exceptions in Debug state* on page H2-4724

Note

`SMC` must not generate a Secure Monitor Call exception from Non-secure state if EDSCR.SDD is set to 1.

Instructions that explicitly write to the PC (branches)

These instructions are:

- `B, B` (conditional), `CBZ, CBNZ BL`.
- `BX, BLX` (register or immediate).
- `BXJ, TBB, TBH`.
- `MOV pc` and related instructions.
- `LDR pc, LDM` (with a register list includes the PC), `POP` (with a register list that includes the PC).

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state without branching and set DSPSR and DLR to UNKNOWN values.

Exception return and related instructions

These instructions are:

- SRS, RFE, SUBS pc, lr, and related instructions.

  Note

  The T32 ERET instruction is decoded as DRPS and is not included in this list.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state without branching, setting DSPSR_EL0 and DLR_EL0 to UNKNOWN values, and either:
  - Execute as DRPS instead of performing an exception return, using UNKNOWN SPSR values.
  - Not changing Exception level or PE mode.

Note

The T32 ERET instruction is decoded as DRPS and is not included in this list.

Instructions that explicitly modify PSTATE, other than DCPS and DRPS

These instructions are:

- CPS, SETEND, IT.
- MSR CPSR (register or immediate).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state, setting DSPSR_EL0 and DLR_EL0 to UNKNOWN values.

Instructions that suspend execution

These instructions are:

- WFE, WFI.

These instructions behave in one of the following ways:

- Are UNDEFINED.
- Execute as a NOP.
- Generate a synchronous exception if the corresponding instruction would be trapped in Non-debug state. See *Configurable instruction enables and disables, and trap controls* on page G1-3742.

  Note

  This means that these instructions must not suspend execution.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Instructions that read the PC

These instructions are:

- `LDR` (literal), `LDRB` (literal), `LDRH` (literal), `LDRSB` (literal), `LDRSH` (literal).
- `ADR`, `ADRL`, `ADRH`.
- `PLD` (literal), `PLI` (literal).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They execute as in Non-debug state using an UNKNOWN value for the PC operand.

Instructions that read PSTATE.{N, Z, C, V} or other PSTATE fields

These instructions are:

- `SEL`, `VSEL`.
- `ADC`, `SBC`, all instructions with an `RRX` shift.
- `MRS CPSR`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They execute as in Non-debug state:
  - For the conditional operations and those using the PSTATE.C flag as an input, these instructions use an UNKNOWN value for the condition flag.
  - For the `MRS` instruction, they return an UNKNOWN value

Instructions that explicitly modify PSTATE.{N, Z, C, V, Q, GE}

These instructions are:

- `CMP`, `TST`, `TEQ`, `CMN`.
- `<opc>S`.
- `MRC p14,0,APSR_nzcv,c0,c1,0` (DBGDSCRint).
- `MSR CPSR`, `MSR APSR`, (register or immediate).
- `VMRS APSR_nzcv,FPSCR`.
- `QADD`, `QDADD`, `QSUB`, `QDSUB`.
- `SMLABB`. `SMLABT`, `SMLATB`, `SMLATT`, `SMLAD`, `SMLAWB`, `SMLAWT`, `SMLSD`, `SMUAD`.
- `SSAT`, `SSAT16`, `USAT`, `USAT16`.
- `SADD`, `SADD8`, `SADD16`, `SASX`, `SSAX`, `SSUB`, `SSUB8`, `SSUB16`.
- `UADD`, `UADD8`, `UADD16`, `UASX`, `USAX`, `USAUB`, `USUN8`, `USUB16`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They execute as in Non-debug state, setting DSPSR_EL0 and DLR_EL0 to UNKNOWN values.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

All other instructions

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They have the same behavior as in Non-debug state.

Note

This includes instructions defined as UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Non-debug state. These instructions are CONSTRAINED UNPREDICTABLE in Debug state. This includes some T32 instructions that specify R15 as a destination or source register, such as:

```
MOV.W R15, #<uimm16>
LDREX R15, [Rn]
```

Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors* describes the CONSTRAINED UNPREDICTABLE behavior for these instructions. In Debug state these CONSTRAINED UNPREDICTABLE choices are further restricted:

- Instructions that specify R15 as a destination register:
  - Are not permitted to branch, because the architecture does not define a branch operation in Debug state.
  - Might set DLR and DSPSR to UNKNOWN values.
  - Might have any of the other permitted behaviors.
- Instructions that specify R15 as a source operand:
  - Cannot use PC + offset, because there is no architecturally-defined PC in Debug state.
  - Might have any of the other permitted behaviors, including using an UNKNOWN value.

H2.4.3 Decode tables

The syntax in the tables is defined as follows:

1 The bit has a fixed value of 1.

0 The bit has a fixed value of 0.

!= The field has any value other than the value or values specified. The field might be an encoding field in the instruction whose value is supplied by the debugger.

Note

The instruction encodings in Chapter C6 *A64 Base Instruction Descriptions* and Chapter F5 *T32 and A32 Base Instruction Set Instruction Descriptions* might show these bits as (0) or (1). A debugger must set these bits to 0 or 1, as appropriate.

Any other value indicates an encoding field in the instruction whose value is supplied by the debugger. Some values might be reserved or UNDEFINED, in which case the instruction is UNDEFINED or CONSTRAINED UNPREDICTABLE in Debug state, as it is in Non-debug state.

For more information about the instruction encodings, see:

- Chapter C6 *A64 Base Instruction Descriptions*.
- Chapter F5 *T32 and A32 Base Instruction Set Instruction Descriptions*.

For information about the syntax used in Table H2-2 on page H2-4717, Table H2-3 on page H2-4717, Table H2-4 on page H2-4718, and Table H2-5 on page H2-4719, see:

- *Common syntax terms* on page C1-121.
- *Assembler symbols* on page F2-2320.

H2.4.4 Security in Debug state

If EL3 is implemented or the implemented Security state is Secure state, security in Debug state is governed by the Secure debug disabled flag, EDSCR.SDD.

On entry to Debug state

If entering in Secure state, EDSCR.SDD is set to 0. Otherwise EDSCR.SDD is set to the inverse of `ExternalSecureInvasiveDebugEnabled()`. That is:

- If `ExternalSecureInvasiveDebugEnabled()` == TRUE, EDSCR.SDD is set to 0.
- If `ExternalSecureInvasiveDebugEnabled()` == FALSE, EDSCR.SDD is set to 1.

Note

Normally, if `ExternalSecureInvasiveDebugEnabled()` == FALSE then halting is prohibited and it is not possible to enter Debug state from Secure state. However, because changes to the authentication signals require a *Context synchronization operation* to guarantee their effect, there is a period during which the PE might halt even though the authentication signals prohibit halting.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

In Debug state

The value of EDSCR.SDD does not change, even if `ExternalSecureInvasiveDebugEnabled()` changes.

Note

- DBGAUTHSTATUS_EL1.{SNID, SID, NSNID, NSID} are not frozen in Debug state.
- If EDSCR.SDD set to 1 in Debug state, then there is no means to enter Secure state from Non-secure state. In this case it is impossible for the PE to be in Secure state. This is a general principle of behavior in Debug state.

In Non-debug state

EDSCR.SDD returns the inverse of `ExternalSecureInvasiveDebugEnabled()`. If the authentication signals that control `ExternalSecureInvasiveDebugEnabled()` change, a *Context synchronization operation* is required to guarantee their effect.

Note

- In Non-debug state, EDSCR.SDD is unaffected by the Security state of the PE.
- A *Context synchronization operation* is also required to guarantee that changes in the authentication signals are visible in DBGAUTHSTATUS_EL1.{SNID, SID, NSNID, NSID}.

If EL3 is not implemented and the implemented Security state is Non-Secure state, EDSCR.SDD is RES1.

H2.4.5 Privilege in Debug state

The only additional privileges offered to Debug state are:

- The privilege to execute *Debug state instructions, DCPS, DRPS, MRS, MSR* on page H2-4721.
- The privilege to execute DTR access instructions regardless of the Exception level and traps.

In Non-debug state, the Debug state instructions are UNDEFINED, except for the T32 `DRPS` instruction. The T32 `DRPS` instruction uses the encoding of the Non-debug T32 `ERET` instruction.

In Debug state, the Debug state instructions can be executed at any Exception level. However, there are some cases where the instructions are UNDEFINED. For more information, see *Debug state instructions, DCPS, DRPS, MRS, MSR* on page H2-4721. These instructions generate an Undefined Instruction exception when they are UNDEFINED. If this Undefined Instruction exception is taken to an Exception level using AArch64, it is reported using ESR_ELx.EC, with the code `0x00`, and if taken to AArch32 Hyp mode, reported using HSR.EC `of 0x00`.

The DTR access instructions can be executed at any Exception level, including EL0, regardless of any control register settings that might force these instructions to be UNDEFINED or trapped in Non-debug state. These instruction are:

- The `MRS` and `MSR` instructions that access DBGDTR_EL0, DBGDTRTX_EL0, and DBGDTRRX_EL0 in AArch64 state.
- The `MRC` and `MCR` instructions that access DBGDTRTXint and DBGDTRRXint in AArch32 state.

All other instructions operate with the privilege determined by the current Exception level and security state. This applies to all Special-purpose and System registers accesses, memory accesses, and UNDEFINED instructions, and includes generating exceptions when the System registers trap or disable an instruction.

Non-Confidential - Beta

H2.4.6 Debug state instructions, DCPS, DRPS, MRS, MSR

ARMv8 defines instructions to change between Exception levels in Debug state. These instructions can also change the mode at the current Exception level.

DCPS

Executing a DCPS instruction in Debug state moves the PE to a higher Exception level or to a specific mode at the current Exception level.

If the DCPS instruction is executed in AArch32 state and the target Exception level is using AArch64:

- The current instruction set switches from T32 to A64.
- The effect on registers that are not visible or only partially visible in AArch32 state is the same as for system calls in Non-debug state. See *Execution state* on page D1-1431.

Otherwise, the instruction set state does not change.

If the target Exception level is the same as the current Exception level, then the PE does not change Exception level. However, the PE can change mode.

The effect on endianness is the same as for exceptions and exception returns in Non-debug state:

- In AArch64, the current endianness is set according to SCTLR_ELx.EE for the target Exception level.
- In AArch32, the current endianness is set according to SCTLR.EE or HSCTLR.EE for the target Exception level.

The assembler syntax for the DCPS instructions is:

```
DCPS1    {#<uimm16>}
DCPS2    {#<uimm16>}
DCPS3    {#<uimm16>}
```

<uimm16> is only available in the A64 encoding and is ignored by hardware.

The decode can be found in the instruction descriptions for DCPS1, DCPS2, and DCPS3 for A64, and DCPS1, DCPS2, DCPS3 for T32.

DCPS is UNDEFINED in Non-debug state.

Table H2-6 on page H2-4722 shows the target of the instruction. In Table H2-6 on page H2-4722 the entries have the following meaning:

EL1h/Svc This means that the target is:
- EL1h if EL1 is using AArch64.
- EL1 and Supervisor mode if EL1 is using AArch32.

EL2h/Hyp This means that the target is:
- EL2h if EL2 is using AArch64.
- EL2 and Hyp mode if EL2 is using AArch32.

EL3h/Monitor This means that the target is:
- EL3h if EL3 is using AArch64.
- EL3 and Monitor mode if EL3 is using AArch32.

Svc Secure Supervisor mode, in EL3 using AArch32.

Monitor Secure Monitor mode, in EL3 using AArch32.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Table H2-6 Target for DCPS instructions in Debug state

Instruction	Target when DCPS instruction executed at stated Exception level:				
	EL0	EL1	EL2	EL3 (AArch64)	EL3 (AArch32)
DCPS1	EL1h/Svc	EL1h/Svc	EL2h/Hyp	EL3h	Svc, clears NS to 0
DCPS2	EL2h/Hyp	EL2h/Hyp	EL2h/Hyp	EL3h	UNDEFINED
DCPS3	EL3h/Monitor	EL3h/Monitor	EL3h/Monitor	EL3h	Monitor, clears NS to 0

Note

- In AArch32 Monitor mode, DCPS1 and DCPS3 clear SCR.NS to 0.
- In AArch64, at EL3, DCPS does not change SCR_EL3.NS.

However:

- DCPS1 is UNDEFINED at EL0 in Non-secure state if both:
  - EL2 is implemented.
  - HCR_EL2.TGE == 1.
- DCPS2 is UNDEFINED at all Exception levels if EL2 is not implemented.
- DCPS2 is UNDEFINED at the following Exception levels if EL2 is implemented:
  - At EL0 and EL1 in Secure state.
  - At EL3 if EL3 is using AArch32.
- DCPS3 is UNDEFINED at all Exception levels if either:
  - EDSCR.SDD == 1.
  - EL3 is not implemented.

The `DCPS` instructions are also defined in T32, see *DCPS1, DCPS2, DCPS3* on page F5-2570. There is no A32 encoding.

On executing a `DCPS` instruction:

- If the target Exception level is using AArch64:
  - ELR_ELx of the target Exception level becomes UNKNOWN.
  - SPSR_ELx of the target Exception level becomes UNKNOWN.
  - ESR_ELx of the target Exception level becomes UNKNOWN.
  - DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- If the target Exception level is using AArch32 DLR and DSPSR become UNKNOWN and:
  - If the target Exception level is EL1 or EL3, the LR and SPSR of the target mode become UNKNOWN.
  - If the target Exception level is EL2, then ELR_hyp, SPSR_hyp, and HSR become UNKNOWN.

If the target Exception level is using AArch32, and the target Exception level is EL1 or EL3, the LR and SPSR of the target mode become UNKNOWN.

The `DCPSInstruction()` function is described in Chapter J1 *ARMv8 Pseudocode*.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

DRPS

Executing the DRPS instruction in Debug state moves the PE to a lower Exception level, or to another PE mode at the current Exception level, by copying the current SPSR to PSTATE.

If DRPS is executed in AArch64 state and the target Exception level is using AArch32:

- The current instruction set switches from A64 to T32.
- The effect on registers that are not visible or only partially visible in AArch32 state is the same as for exception returns in Non-debug state. See *Execution state* on page D1-1431.

Otherwise the instruction set state does not change.

If the target Exception level is the same as the current Exception level, then the PE does not change Exception level. However, the PE can change mode.

The effect on endianness is the same as for exceptions and exception returns in Non-debug state:

- If targeting an Exception level using AArch64, current endianness is set according to SCTLR_ELx.EE, or SCTLR_EL1.E0E for the target Exception level.
- If targeting an Exception level using AArch32, current endianness is set by SPSR.E as appropriate.

The assembler syntax for the DRPS instruction is:

```
DRPS
```

The decode can be found in the instruction description for DRPS.

If the SPSR specifies an illegal exception return, then PSTATE.{M, nRW, EL, SP} are unchanged and PSTATE.IL is set to 1. For further information on illegal exception returns, see *Illegal return events from AArch64 state* on page D1-1467.

PSTATE.{N, Z, C, V, Q, GE, IT, T, SS, D, A, I, F} are ignored in Debug state. This means that the effect of DRPS on these fields is to set them to an UNKNOWN value that might be the value from the SPSR. For more information see *Process state (PSTATE) in Debug state* on page H2-4705.

All other PSTATE fields are copied from SPSR.

DRPS is UNDEFINED at EL0 and in Non-debug state. In Debug state, the T32 encoding for ERET is decoded as DRPS. There is no A32 encoding for DRPS.

Note

Unlike an exception return, `DRPS` has no architecturally-defined effect on the Event Register and exclusive monitors. `DRPS` might set the Event Register or clear the exclusive monitors, or both, but this is not a requirement and debuggers must not rely on any implementation specific behavior.

On executing a `DRPS` instruction:

- If the target Exception level is using AArch64:
  - DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- If the target Exception level is using AArch32:
  - DLR and DSPSR become UNKNOWN.

The `DRPSInstruction()` function is described in Chapter J1 *ARMv8 Pseudocode*.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

MRS and MSR instructions to access DLR_EL0 and DSPSR_EL0

The other Debug state instructions are MRS and MSR (register) instructions to read or write DLR_EL0 and DSPSR_EL0, and the equivalent MRC and MCR operations in AArch32 state.

```
MRS <Xt>, DLR_EL0      ; Copy DLR_EL0 to <Xt>
MRS <Xt>, DSPSR_EL0    ; Copy DSPSR_EL0 to <Xt>
MSR DLR_EL0, <Xt>      ; Copy <Xt> to DLR_EL0
MSR DSPSR_EL0, <Xt>    ; Copy <Xt> to DSPSR_EL0
```

These instructions can be executed at any Exception level when in Debug state, including EL0. They are UNDEFINED in Non-debug state.

H2.4.7 Exceptions in Debug state

The following sections describe how exceptions are handled in Debug state:

- *Generating exceptions when in Debug state*.
- *Taking exceptions when in Debug state* on page H2-4725.
- *Reset in Debug state* on page H2-4726.

Generating exceptions when in Debug state

In Debug state:

- Instruction Abort exceptions cannot happen because instructions are not fetched from memory.
- Interrupts, including SError and virtual interrupts are ignored and remain pending:
  - The pending interrupt remains visible in ISR.
- Debug exceptions are ignored.
- SCR.EA is treated as if it were set to 0, regardless of its actual state, other than for the purpose of reading the bit.
- All instruction bit patterns that are an allocated instruction at the current Exception level, but listed in *Executing instructions in Debug state* on page H2-4705 as UNDEFINED in Debug state, generate Undefined Instruction exceptions, which are taken to the current Exception level, or to EL1 if executing at EL0. This includes SVC, HVC, SMC, BRK, and HLT. The priority and syndrome for these exceptions is the same as for executing an encoding that does not have an allocated instruction.
- Instructions executed at EL2, EL1 and EL0 that are configured by EL3 control registers to trap to EL3:
  - Generate the appropriate trap exception taken to EL3 if EDSCR.SDD == 0.
  - Generate an Undefined Instruction exception taken to the current Exception level, or to EL1 if executing at EL0, if EDSCR.SDD == 1. If the exception is taken to an Exception level using AArch64 or to AArch32 Hyp mode, this is reported with an exception class of 0x00.

  Otherwise configurable traps, enables, and disables, for instructions are unaffected by Debug state, and executing the affected instructions generates the appropriate exceptions.

Otherwise, synchronous exceptions, including Data Aborts, are generated as they would be in Non-debug state and taken to the appropriate Exception level in Debug state.

Note

If EDSCR.SDD == 1 then an exception from Non-secure state is never taken to Secure state. See *Security in Debug state* on page H2-4719.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Taking exceptions when in Debug state

When the PE is in Debug state, all exceptions are synchronous. When an exception is generated, it is taken to Debug state. This means that:

- The target Exception level is as defined for the exception in Non-debug state.
- If the target Exception level is using AArch32 then the target PE mode is as defined for the exception in Non-debug state.
- The exception syndrome is reported as defined for the exception in Non-debug state, except for the case described in *Data Aborts in Memory access mode* on page H4-4763 for which the reporting requirements are relaxed.

  The exception syndrome is reported using the syndrome register or registers for the target Exception level. In AArch64, these are ESR_ELx, and FAR_ELx. In AArch32, these are DFSR, DFAR, HSR, HDFAR, and HPFAR. For example:

  — If a Data Abort exception is taken to Abort mode at EL1 or EL3 and the exception is taken from AArch32 state and using the Short-descriptor translation table format, the DFSR reports the exception using the Short-descriptor format fault encoding. For exceptions other than Data Abort exceptions taken to Abort mode, DFSR is not updated.

  — If an instruction is trapped to an Exception level using AArch64 due to a configurable trap, disable, or enable, the exception code reported is the same as it would be in Non-debug state.

  The effect on auxiliary syndrome registers, such as AFSR, is IMPLEMENTATION DEFINED.

  Note

  Generally, the AArch32 Fault Address Registers (FARs) and Fault Status Registers (FSRs) are not described as *syndrome registers*, although the term is appropriate to their function.

- The PE remains in Debug state and changes to the target mode.
- If EL3 is using AArch32 and the exception is taken from Monitor mode, SCR.NS is cleared to 0.
- If the exception is taken to an Exception level using AArch32, the PE continues to execute T32 instructions, regardless of the TE bit in the System register for the target Exception level.
- The endianness switches to that indicated by the EE bit of the System register for the target Exception level.
- The SPSR for the target Exception level or mode is corrupted and becomes UNKNOWN.
- If the target Exception level is using AArch64, ELR_ELx for the target Exception level becomes UNKNOWN.
- If the target Exception level is EL2 using AArch32, ELR_hyp becomes UNKNOWN.
- If the target Exception level is EL1 or EL3 using AArch32, LR_<mode> for the target mode becomes UNKNOWN.
- DLR and DSPSR become UNKNOWN.
- The cumulative error flag, EDSCR.ERR, is set to 1. See *Cumulative error flag* on page H4-4767.
- PSTATE.IL is cleared to 0.
- PSTATE.{IT, T, SS, D, A, I, F} are set to UNKNOWN values, and PSTATE.{N, Z, C, V, Q, GE} are unchanged. However, these fields are ignored and are not observable in Debug state. For more information see *Process state (PSTATE) in Debug state* on page H2-4705.

The debugger must save any state that can be corrupted by an exception before executing an instruction that might generate another exception.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Pseudocode description of taking exceptions in Debug state

The pseudocode function AArch64.TakeException() shows the behavior when the PE takes an exception to an Exception level using AArch64 in Non-debug state. In Debug state, this is replaced with the function AArch64.TakeExceptionInDebugState().

The pseudocode functions AArch32.EnterMode(), AArch32.EnterHypMode(), and AArch32.EnterMonitorMode() show the behavior when the PE takes an exception to an Exception level using AArch32 in Non-debug state. In Debug state:

- AArch32.EnterMode() is replaced with the function AArch32.EnterModeInDebugState().
- AArch32.EnterHypMode() is replaced with the function AArch32.EnterHypModeInDebugState().
- AArch32.EnterMonitorMode() is replaced with AArch32.EnterMonitorModeInDebugState().

Reset in Debug state

If the PE is reset when in Debug state, it exits Debug state and enters Non-debug reset state. When the PE is in reset state, EDSCR.STATUS == 0b000010 and writes to EDITR are ignored.

Note

If EDECR.RCE == 1, meaning that a Reset Catch debug event is programmed, and if halting is allowed on exiting reset state, then on exiting reset state the PE halts and re-enters Debug state. See *Reset Catch debug events* on page H3-4752. All PE registers have taken their reset values, which might be UNKNOWN.

H2.4.8 Accessing registers in Debug state

Register accesses are unchanged in Debug state. The view of each register is determined by either the current Exception level or the mode, or both, and accesses might be disabled or trapped by controls at a higher Exception level.

General-purpose register access, other than SP access in AArch64 state

A single general-purpose register can be read by issuing an MSR instruction through the ITR to write DBGDTR_EL0 in AArch64 state, or an MCR instruction through the ITR to write DBGDTRTXint in AArch32 state. The debugger can then read the DTR register or registers through the external debug interface. The reverse sequence writes to a general-purpose register.

Figure H2-1 on page H2-4727 shows the reading and writing of general-purpose registers, other than SP, in Debug state in AArch64 state.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.

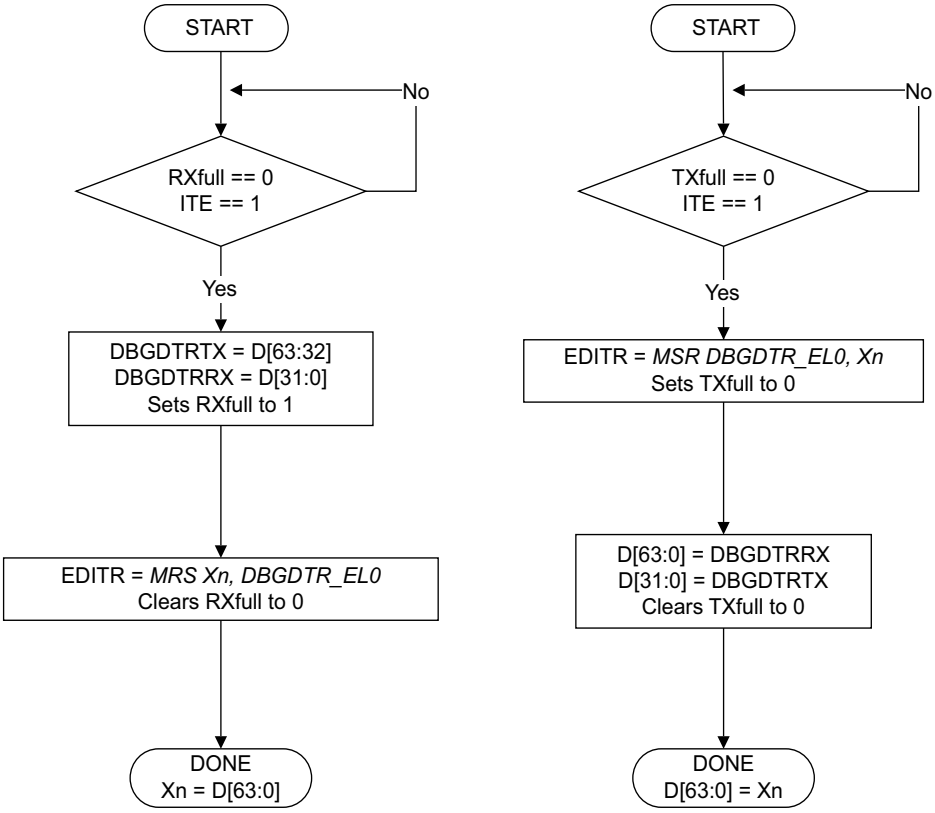

Figure H2-1 Reading and writing general-purpose registers, other than SP, in Debug state in AArch64 state

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Figure H2-2 shows the reading and writing of general-purpose registers in Debug state in AArch32 state.

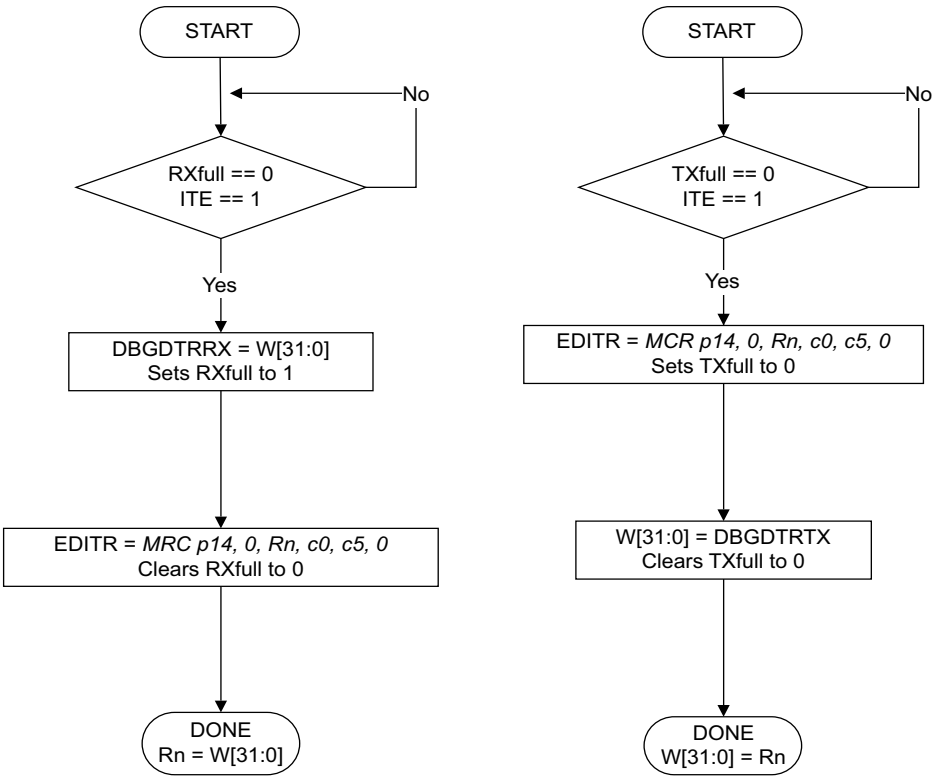

Figure H2-2 Reading and writing general-purpose registers in Debug state in AArch32 state

SIMD and floating-point register, System register, and SP accesses in AArch64 state

To read a SIMD and floating-point register or a System register, the debugger must first copy the value into a general-purpose register using:

- An `FMOV` instruction in AArch64 or a `VMOV` instruction in AArch32 for floating-point transfers to SIMD and FP registers.
- A `UMOV` instruction in AArch64 or a `VMOV` instruction in AArch32 for SIMD transfers to SIMD and FP registers.
- An `MRS` instruction in AArch64 or an `MRC` instruction in AArch32 for System registers.
- A `MOV Xd,SP` instruction for the SP register in AArch64 state.

The debugger can then read out the particular general-purpose register. The reverse sequence writes a register.

PC and PSTATE access

The debugger reads the program counter and PSTATE of the process being debugged through the DLR_EL0 and DSPSR_EL0 System registers. The actual values of PC and PSTATE cannot be directly observed in Debug state:

- Instructions that are used for direct reads and writes of PC and PSTATE in Non-debug state are UNDEFINED in Debug state.
- On taking an exception, ELR_ELx and SPSR_ELx at the target exception level are UNKNOWN. They do not record the PC and PSTATE.

PSTATE.{IL, E, M, nRW, EL, SP} are indirectly read by instructions executed in Debug state, but all other PSTATE fields are ignored and cannot be observed. See also:

- *Process state (PSTATE) in Debug state* on page H2-4705.
- *Executing instructions in Debug state* on page H2-4705.
- *Exceptions in Debug state* on page H2-4724.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H2.4.9 Accessing memory in Debug state

How the PE accesses memory is unchanged in Debug state. This includes:

- The operation of the MMU, including address translation, tagged address handling, access permissions, memory attribute determination, and the operation of any TLBs.
- The operation of any caches and coherency mechanisms.
- Alignment support.
- Endianness support.
- The Memory order model.

Simple memory transfers

Simple memory accesses can be performed in Debug state by issuing memory access instructions through the ITR and passing data through the DTR registers. *Executing instructions in Debug state* on page H2-4705 lists the memory access instructions that are supported in Debug state.

Bulk memory transfers

Memory access mode can accelerate bulk memory transfers in Debug state. See *DCC and ITR access modes* on page H4-4761.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H2.5 Exiting Debug state

The PE exits Debug state when it receives a Restart request trigger event. If EDSCR.ITE == 0 the behavior of any instruction issued through the ITR in Normal access mode or an operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state after the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

Note

- Implementations can set EDSCR.ITE to 1 to indicate that further instructions can be accepted by ITR before the previous instructions have completed. If any previous instruction has not completed and EDSCR.ITE == 1, then the PE must complete these instructions in Debug state before executing the restart sequence. EDSCR.ITE == 0 indicates that the PE is not ready to restart.
- A debugger must observe that any instructions issued through EDITR that might generate a synchronous exception, as complete, before issuing a restart request. It can do this by observing the completion of a later instruction, as synchronous exceptions must occur in program order. For example, a debugger can observe that an instruction that reads or writes a DTR register is complete because of its effect on the EDSCR.{TXfull, RXfull} flags.

On exiting Debug state, the PE sets the program counter to the address in DLR, where:

- If exiting to AArch32 state:
  - Bits[63:32] of DLR are ignored.
  - Bits[31:1] of the PC are set to the value of bits[31:1] of DLR.
  - Bit[0] of the PC is set to a CONSTRAINED UNPREDICTABLE choice of 0 or the value of bit[0] in DLR.
- If exiting to AArch64 state:
  - Bits[63:56] of DLR_EL0[31:0] might be ignored as part of tagged address handling. See *Address tagging in AArch64 state* on page D4-1646.
  - Otherwise the PC is set from DLR_EL0[31:0].

Exit from Debug state can give rise to a misaligned PC exception when the program counter is used. Unlike an exception return, this might also happen when returning to AArch32 state. For more information, see *PC alignment checking* on page D1-1445.

On exiting Debug state, PSTATE is set from DSPSR in the same way that an exception return sets PSTATE from SPSR_ELx:

- The same illegal exception return checks that apply to an exception return also apply to exiting Debug state. If the return from Debug state is an illegal exception return then the effect on PSTATE and the PC is the same as for any other illegal exception return. See *Exception return* on page D1-1466 and *Exception return to an Exception level using AArch32* on page G1-3692.
- The checks on the PSTATE.IT bits that apply to exiting Debug state into AArch32 state are the same as those that apply to an exception return. See Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- PSTATE.SS is copied from DSPSR.SS if all of the following hold:
  - MDSCR_EL1.SS == 1.
  - The debug target Exception level is using AArch64.
  - Software step exceptions from the restart Exception level are enabled.

  Otherwise PSTATE.SS is set to 0.

  Note

  Unlike a return using ERET, PSTATE.SS must be restored from DSPSR.SS because otherwise it is UNKNOWN.

  However, if OSDLR.DLK == 1 and DBGPRCR.CORENPDRQ == 0, meaning the OS Double Lock is locked in Non-debug state and therefore Software Step exceptions are disabled, but otherwise Software Step exceptions would be enabled from the restart Exception level, it is CONSTRAINED UNPREDICTABLE whether PSTATE.SS is copied from DSPSR.SS.

Note

- One important difference between Debug state exit and an exception return is that the PE can exit Debug state at EL0. Despite this, the behavior of an exit from Debug state is similar to an exception return. For example, PSTATE.{D, A, I, F} is updated regardless of the value of SCTLR_EL1.UMA.
- Exit from Debug state has no architecturally-defined effect on the Event Register and exclusive monitors. An exit from Debug state might set the Event Register or clear the exclusive monitors, or both, but this is not a requirement and debuggers must not rely on any implementation specific behavior.

The `ExitDebugState()` function is described in Chapter J1 *ARMv8 Pseudocode*.

Chapter H3
Halting Debug Events

This chapter describes a particular class of debug events. It contains the following sections:

- *Introduction to Halting debug events* on page H3-4734.
- *Halting Step debug events* on page H3-4736.
- *Halt Instruction debug event* on page H3-4746.
- *Exception Catch debug event* on page H3-4747.
- *External Debug Request debug event* on page H3-4750.
- *OS Unlock Catch debug event* on page H3-4751.
- *Reset Catch debug events* on page H3-4752.
- *Software Access debug event* on page H3-4753.
- *Synchronization and Halting debug events* on page H3-4754.

Note

Table K13-1 on page K13-5568 disambiguates the general register references used in this chapter.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H3.1 Introduction to Halting debug events

External debug defines Halting debug events. The following Halting debug events are available in ARMv8:

- *Halting Step debug events* on page H3-4736.
- *Halt Instruction debug event* on page H3-4746.
- *Exception Catch debug event* on page H3-4747.
- *External Debug Request debug event* on page H3-4750.
- *OS Unlock Catch debug event* on page H3-4751.
- *Reset Catch debug events* on page H3-4752.
- *Software Access debug event* on page H3-4753.

If halting is allowed, a Halting debug event halts the PE. The PE enters Debug state.

In addition, breakpoints and watchpoints might halt the PE if halting is allowed. See *Breakpoint and Watchpoint debug events* on page H2-4696. Because breakpoints and watchpoints can generate an exception or halt the PE, Breakpoint and Watchpoint debug events are not classified as Halting debug events.

For a definition of Debug state, see Chapter H2 *Debug State*. For a definition of halting allowed, see *Halting allowed and halting prohibited* on page H2-4695.

Debug state entry and debug event prioritization on page H2-4697 describes the behavior when multiple debug events are generated by an instruction.

See also *Synchronization and Halting debug events* on page H3-4754.

Table H3-1 shows the behavior of Breakpoint, Watchpoint, and Halting debug events.

Table H3-1 Summary of debug events and possible outcomes

Debug event type	PE behavior when halting is:	
	Allowed	Prohibited
Breakpoint and Watchpoint debug events on page H2-4696	Halt	See Table D2-1 on page D2-1557 and Table G2-1 on page G2-3781
Halt Instruction debug event on page H3-4746	Halt	UNDEFINED
Software Access debug event on page H3-4753	Halt	Ignored
Exception Catch debug event on page H3-4747	Halt	Ignored
Halting Step debug events on page H3-4736	Halt	Pended
External Debug Request debug event on page H3-4750	Halt	Pended
Reset Catch debug events on page H3-4752	Halt	Pended
OS Unlock Catch debug event on page H3-4751	Pended	Pended

Table H3-2 shows where the pseudocode for each Halting debug event type is located.

Table H3-2 Pseudocode description of Halting debug events

Halting debug event type	Pseudocode
Halt Instruction debug event on page H3-4746	*HLT* on page C6-524 for AArch64 and *HLT* on page F5-2587 for AArch32

H3.2 Halting Step debug events

Halting Step is a debug resource that a debugger can use to make the PE step through code one instruction at a time. This section describes the Halting Step debug events. It is divided into the following sections:

- *Overview of a Halting Step debug event*.
- *The Halting Step state machine*.
- *Using Halting Step* on page H3-4739.

The architecture describes the behavior as a simple Halting Step state machine. See *The Halting Step state machine*.

H3.2.1 Overview of a Halting Step debug event

The behavior of Halting Step is defined by a state machine, shown in Figure H3-1 on page H3-4738. A Halting Step debug event executes a single instruction and then returns control to the debugger. When the debugger software wants to execute a Halting Step:

1. With the PE in Debug state, the debugger activates Halting Step.
2. The debugger signals the PE to exit Debug state and return to the instruction that is to be stepped.
3. The PE executes that single instruction.
4. The PE enters Debug state before executing the next instruction.

However, an exception might be generated while the instruction is being stepped. That is either:

- A synchronous exception generated by the instruction being stepped.
- An asynchronous exception taken before or after the instruction being stepped.

Halting Step has its own enable control bit, EDECR.SS and EDESR.SS.

Note

Because the Halting Step state machine states occur as a result of normal PE operation, the states can be described as both:

- PE states.
- Halting Step states.

H3.2.2 The Halting Step state machine

The state machine states are:

Inactive Halting Step is inactive. No Halting Step debug events can be generated, therefore execution is not affected by Halting Step. The PE is in this state whenever either of the following is true:

- Halting Step is disabled. That is, EDECR.SS is set to 0 and EDESR.SS is set to 0.
- Halting is prohibited. See *Halting the PE on debug events* on page H2-4695.

In Figure H3-1 on page H3-4738 this state is shown in red.

Active-not-pending

Halting Step is enabled and active. This is the state in which the PE steps an instruction. EDECR.SS == 1 and EDESR.SS == 0. Software must not set EDECR.SS to 1 unless the PE is in Debug state, otherwise behavior is CONSTRAINED UNPREDICTABLE, as described in *Setting the value of EDECR.SS to 1 when not in Debug state* on page K1-5380.

In Figure H3-1 on page H3-4738 this state is shown in green.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Active-pending

Halting Step is enabled and active. The step has completed, and the PE enters Debug state. EDESR.SS == 1.

In Figure H3-1 on page H3-4738 this state is shown in green.

Whenever Halting Step is enabled and active, whether the state machine is in the active-not-pending state or in the active-pending state depends on EDESR.SS. *Halting Step state machine states* on page H3-4739 shows this.

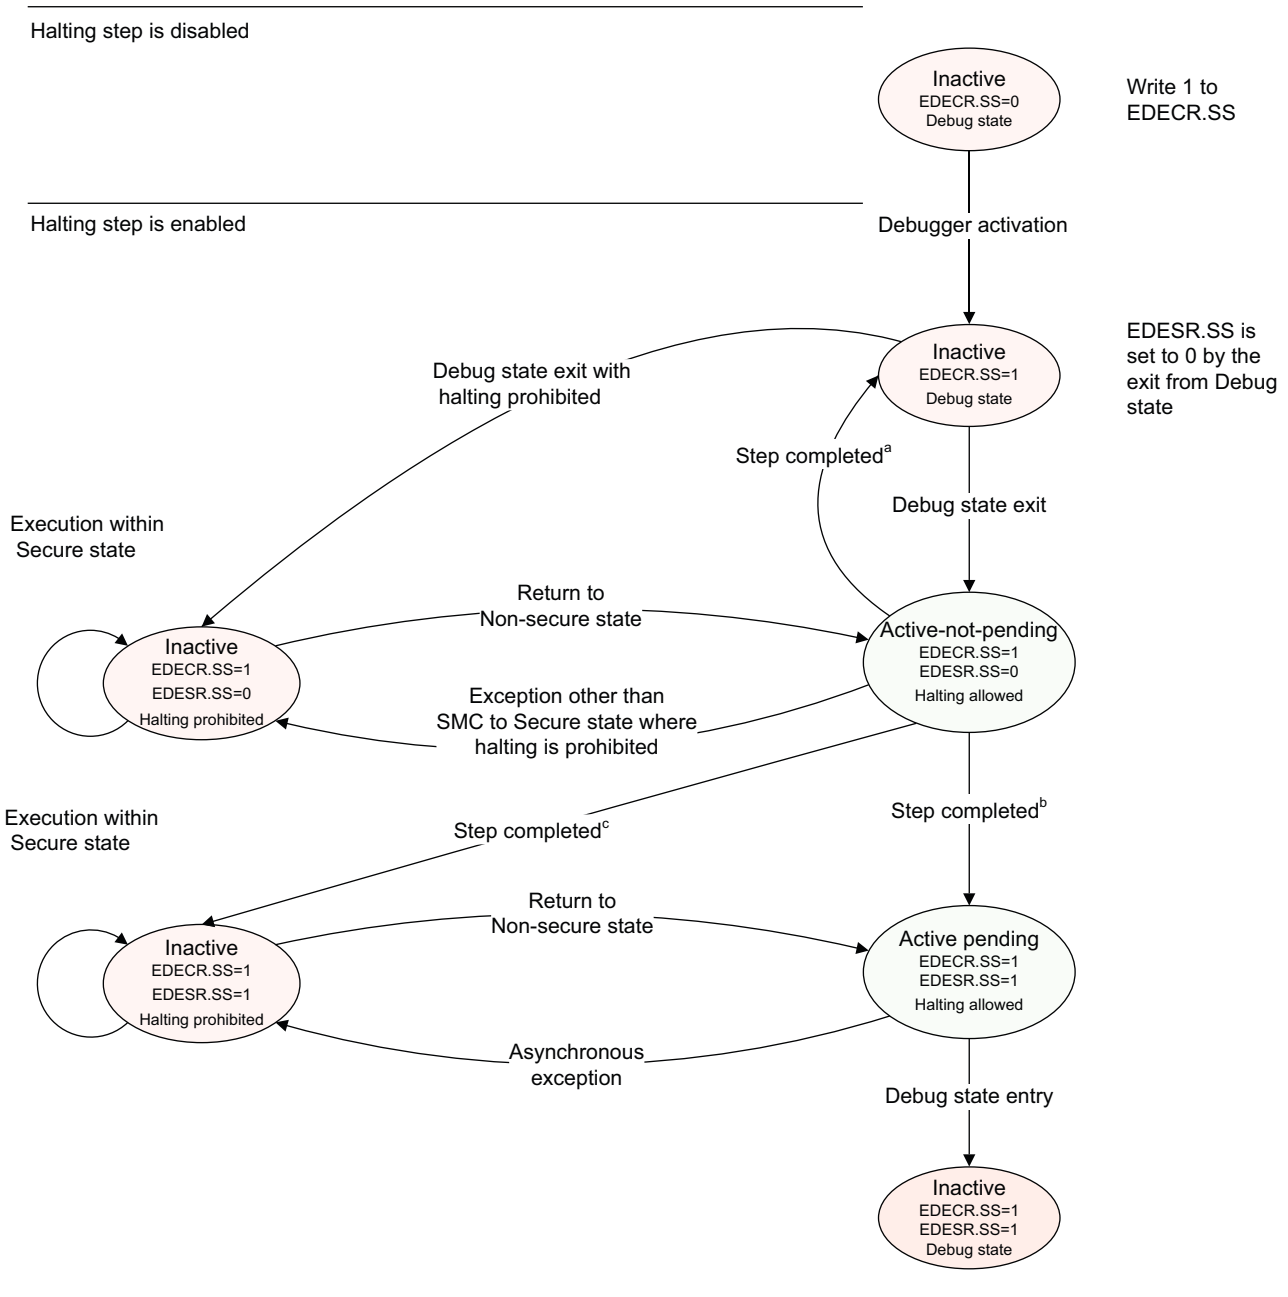
In the simple sequential execution of the program the PE executes the Halting Step state machine, as follows:

1. Initially, Halting Step is inactive.
2. After exiting Debug state, Halting Step is active-not-pending.
3. The PE executes an instruction and Halting Step is active-pending.
4. The pending Debug state entry is taken on the next instruction and the step is complete.

Exceptions and other changes to the PE context can interrupt this sequence.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Figure H3-1 shows a Halting Step state machine.



a. Step completed occurs when:
   - A debug event, other than a Halting Step debug event, causes entry into Debug state.

b. Step completed occurs when:
   - An instruction is executed without taking an exception.
   - An exception is taken to a state where halting is allowed.
   - A reset.

c. Step completed occurs when:
   - An SMC exception is taken to Secure state where halting is prohibited.

Figure H3-1 Halting Step state machine

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Note

Figure H3-1 on page H3-4738 only describes state transitions to and from the inactive state by exit from Debug state, executing an exception return, or taking an exception. Other changes to the PE context, including writes to registers such as EDECR and OSDLR and changes to the authentication interface can also cause changes to the Halting Step state machine. These can lead to UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior. See *Synchronization and the Halting Step state machine* on page H3-4742.

The following bits control the state machine, as shown in Table H3-3:

- EDECR.SS. This is the Halting Step enable bit.

  Note

  — The EDECR value is preserved over powerdown, meaning that the step active state is maintained over a powerdown event.

  — A debugger must only set EDECR.SS to 1 when the PE is in Debug state, otherwise behavior is CONSTRAINED UNPREDICTABLE as described in *Setting the value of EDECR.SS to 1 when not in Debug state* on page K1-5380.

- EDESR.SS.

Table H3-3 shows the Halting Step state machine states. The letter X in a register column means that the relevant bit can be set to either zero or one.

Table H3-3 Halting Step state machine states

Halting	EDECR.SS	EDESR.SS	Halting Step state
Prohibited	X	X	Inactive
Allowed	0	0	Inactive
Allowed	1	0	Active-not-pending
Allowed	X	1	Active-pending

H3.2.3 Using Halting Step

To step a single instruction the PE must be in Debug state:

1. The debugger sets EDECR.SS to 1 to enable Halting step.
2. The debugger signals the PE to exit Debug state with DLR set to the address of the instruction being stepped. The PE clears EDESR.SS to 0 and the Halting Step state machine enter the active-not-pending state.
3. The PE executes the instruction being stepped.

   If an exception is taken to a state where halting is prohibited, then EDESR.SS is always correct for the preferred return address of the exception.
4. The PE enters Debug state before executing the next instruction and the step is complete.

H3.2.4 Detailed Halting Step state machine behavior

The behavior of the Halting Step state machine is described in the following sections:

- *Entering the active-not-pending state* on page H3-4740.
- *PE behavior in the active-not-pending state* on page H3-4740.
- *Entering the active-pending state* on page H3-4741.
- *PE behavior in the inactive state when in Non-debug state* on page H3-4742.
- *PE behavior in Debug state* on page H3-4742.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Entering the active-not-pending state

The PE enters the active-not-pending state:

- By exiting Debug state with EDECR.SS == 1.
- By an exception return from a state where halting is prohibited to a state where halting is allowed with EDECR.SS == 1 and EDESR.SS == 0.
- As described in *Synchronization and the Halting Step state machine* on page H3-4742.

PE behavior in the active-not-pending state

When the PE is in the active-not-pending state it does one of the following:

- It executes one instruction and does one of the following:
  - Completes it without generating a synchronous exception.
  - Generates a synchronous exception.
  - Generates a debug event that causes entry to Debug state.
- It takes an asynchronous exception without executing any instruction.
- It takes an asynchronous debug event into Debug state.

If no exception or debug event is generated

If no exception or debug event is generated the PE sets EDESR.SS to 1. This means that the Halting Step state machine advances to the active-pending state.

If an exception or debug event is generated

The PE sets EDESR.SS according to all of the following:

- The type of exception.
- The target Exception level of the exception.
- If the exception is taken to Secure state, whether halting is prohibited in Secure state.
  - This is determined by the result of `ExternalSecureInvasiveDebugEnabled()`.

If an exception or debug event is generated, the PE sets EDESR.SS to 1 if one of the following applies:

- A synchronous exception is generated by the instruction and one of the following applies:
  - The exception is taken to EL1 or EL2.
  - The exception is not an SMC exception and `ExternalSecureInvasiveDebugEnabled()` == TRUE.
  - The exception is an SMC exception.
- An asynchronous exception is generated before executing an instruction and this is either:
  - Taken to EL1 or EL2.
  - Taken to EL3 and `ExternalSecureInvasiveDebugEnabled()` == TRUE.
- A PE reset occurs.

Otherwise EDESR.SS is unchanged. This happens when:

- No instruction is executed because either:
  - An asynchronous exception is taken to EL3 and `ExternalSecureInvasiveDebugEnabled()` == FALSE.
  - An asynchronous debug event causes entry to Debug state.
- An instruction is executed and either:
  - Generates a synchronous exception other than an SMC exception which is taken to EL3, and `ExternalSecureInvasiveDebugEnabled()` == FALSE.
  - Generates a synchronous debug event and causes entry to Debug state.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

If halting is prohibited after taking the exception or debug event, then the Halting Step state machine advances to the inactive state. Otherwise the Halting Step state machine advances to the active-pending state.

Note

The underlying criteria for the value of EDESR.SS on an exception are:

- Whether halting is allowed at the target of the exception. If halting is allowed, the PE must step into the exception. If halting is prohibited, the PE must step over the exception.
- Whether the preferred return address of the exception is the instruction itself or the next instruction, if the PE steps over the exception.

Table H3-4 shows the behavior of the active-not-pending state. The letter X indicates that `ExternalSecureInvasiveDebugEnabled()` can be either TRUE or FALSE.

Table H3-4 Summary of active-not-pending state behavior

Event	Target Exception level	`ExternalSecureInvasiveDebugEnabled()`	Value written to EDESR.SS
No exception or debug event	Not applicable	X	1
SMC exception	EL3	X	1
Reset	Highest	X	1
Exception, other than SMC exception	EL1	X	1
	EL2	X	1
	EL3	TRUE	1
		FALSE	Unchanged
Debug event	Debug state	X	Unchanged

Entering the active-pending state

The PE enters the active-pending state by one of the following:

- From the active-not-pending state by:
  - Executing an instruction without taking an exception.
  - Taking an exception so that the PE remains in a state where halting is allowed.
- An exception return from a state where halting is prohibited when EDESR.SS == 1.

  Note

  That is, an exception return from Secure state with `ExternalSecureInvasiveDebugEnabled()` == FALSE to Non-secure state with `ExternalInvasiveDebugEnabled()` == TRUE.
- A reset when the value of EDECR.SS == 1, regardless of the state the PE was in before the reset occurred.
- Following the description in *Synchronization and the Halting Step state machine* on page H3-4742.

When the PE is in the active-pending state, it enters Debug state before executing an instruction. However, if `ExternalSecureInvasiveDebugEnabled()` == FALSE, the architecture does not define the prioritization of this Debug state entry with respect to any pending asynchronous exception that is taken from Non-secure state to EL3.

If an exception is prioritized over the halt, then EDESR.SS is unchanged. On return from the exception the Halting Step state machine re-enters the active-pending state.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

The entry into Debug state has higher priority than all other types of exception, including all other asynchronous exceptions.

Note

This means that it is possible to step a reentrant exception in the exception vector table.

PE behavior in the inactive state when in Non-debug state

EDESR.SS is not updated by the execution of an instruction or the taking of an exception when Halting Step is inactive. This means that EDESR.SS is not changed by an exception handled in a state where halting is prohibited.

On return to a state where halting is allowed, the Halting Step state machine is restored either to the active-pending state or the active-not-pending state, depending on the value of EDESR.SS. The return to a state where halting is allowed is normally by an exception return, which is a *Context synchronization operation*.

See also *Synchronization and the Halting Step state machine*.

PE behavior in Debug state

Halting Step is inactive in Debug state because halting is prohibited, see *Halting allowed and halting prohibited* on page H2-4695.

Entry to Debug state does not change EDESR.SS.

EDESR.SS is cleared to 0 on exiting Debug state as the result of a restart request. If EDECR.SS == 1, Halting Step enters the active-not-pending state.

Note

This means that EDESR.SS is never cleared to 0 by the execution of an instruction in Debug state, or by taking an exception when in Debug state as described in *PE behavior in the active-not-pending state* on page H3-4740, because the Halting Step state machine is not in the active-not-pending state. EDESR.SS can be cleared by a write to EDESR, see the register description.

However, if the PE exits Debug state as the result of a PE reset and EDECR.SS == 1, then Halting Step immediately enters the active-pending state, as EDESR.SS is set to the value of EDECR.SS.

H3.2.5 Synchronization and the Halting Step state machine

The Halting Step state machine also changes state if:

- Halting becomes allowed or prohibited other than by exit from Debug state, an exception return, or taking an exception. This means that halting becomes allowed or prohibited because:
  - The security state changes without an exception return. See *State and mode changes without explicit context synchronization operations* on page G2-3838.
  - The external authentication interface changes.
  - The OS Double Lock status, `DoubleLockStatus()`, changes.
- A write to EDECR when the PE is in Non-debug state changes the value of EDECR.SS.

  Note

  Behavior is CONSTRAINED UNPREDICTABLE if the value of EDECR.SS is changed to 1 when the PE is in Non-debug state, see *Setting the value of EDECR.SS to 1 when not in Debug state* on page K1-5380.
- A write to EDESR when the PE is in Non-debug state clears EDESR.SS to 0.

These operations are guaranteed to take effect only after a *Context synchronization operation*.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

The PE must perform the required behavior of the new state before or immediately following the next *Context synchronization operation*, but it is not required to do so immediately. This means that the PE can perform the required behavior of the old state before the next *Context synchronization operation*. This is illustrated in Example H3-1 and Example H3-2.

Example H3-1 Synchronization requirements 1

EDECR.SS is set to 1 in Debug state, requesting the active-not-pending state on exit from Debug state. On exit from Debug state the PE immediately takes an exception to Secure state. `ExternalSecureInvasiveDebugEnabled() ==` FALSE, meaning that halting is prohibited in Secure state. The PE does not step any instructions but executes the software in Secure state as normal. EDESR.SS remains set to 0. If `ExternalSecureInvasiveDebugEnabled()` subsequently becomes TRUE, meaning that halting is now allowed, the PE must perform the required behavior of the active-not-pending state before or immediately following the next *Context synchronization operation*, but it is not required to do so immediately.

Example H3-2 Synchronization requirements 2

EDECR.SS is set to 1 in Debug state. On exit from Debug the PE executes an `MSR` instruction that sets OSDLR_EL1.DLK to 1 and `DoubleLockStatus()` becomes TRUE. This change requires a *Context synchronization operation* to guarantee its effect, meaning it is CONSTRAINED UNPREDICTABLE whether:

- Halting is allowed:
  - The PE enters Debug state on the next instruction.
- Halting is prohibited:
  - The PE does not enter Debug state.

The value in EDESR.SS depends on whether halting was allowed or prohibited when the write to OSDLR_EL1.DLK completed, and so it might be 0 or 1. If a second `MSR` instruction clears OSDLR_EL1.DLK to 0, the PE must perform the required behavior of the state indicated by EDESR.SS before or immediately following the next *Context synchronization operation*, but it is not required to do so immediately.

See also *Synchronization and Halting debug events* on page H3-4754.

H3.2.6 Stepping T32 `IT` instructions

In an implementation that supports the ITD control, the architecture permits a combination of one T32 `IT` instruction and another 16-bit T32 instruction to be treated as a single 32-bit instruction when the value of the ITD field that applies to the current Exception level is 1.

For the purpose of stepping an item, it is IMPLEMENTATION DEFINED whether:

- The PE considers such a pair of instructions to be one instruction.
- The PE considers such a pair of instructions be two instructions.

It is IMPLEMENTATION DEFINED whether this behavior depends on the value of the applicable ITD bit. For example:

- The debug logic might consider such a pair of instructions as one instruction, regardless of the state of the applicable ITD field.
- The debug logic might consider such a pair of instructions as two instructions, regardless of the state of the applicable ITD field.
- The debug logic might consider such a pair of instructions as one instruction when the value of the applicable ITD field is 1, and as two instructions when the value of the ITD field is 0.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

The ITD control fields are:

HSCTLR.ITD Applies to execution at EL2 when EL2 is using AArch32.

SCTLR.ITD Applies to execution at EL0 or EL1 when EL1 is using AArch32.

SCTLR_EL1.ITD
Applies to execution at EL0 using AArch32 when EL1 is using AArch64.

H3.2.7 Disabling interrupts while stepping

When using Halting Step, the sequence of entering Debug state, interacting with the debugger, and then exiting Debug state for each instruction reduces the rate at which the PE executes instructions. However, the rate at which certain interrupts, such as timer interrupts, are generated might be fixed by the system. This means it might be necessary to disable interrupts while using Halting Step by setting EDSCR.INTdis, to allow the code being debugged to make forward progress.

H3.2.8 Syndrome information on Halting Step

Three EDSCR.STATUS encodings record different scenarios for entering Debug state on a Halting Step debug event:

Halting Step, normal
An instruction other than a Load-Exclusive instruction was stepped.

Halting Step, exclusive
A Load-Exclusive instruction was stepped.

Halting Step, no syndrome
The syndrome data is not available.

If the PE enters Debug state due to a Halting Step debug event immediately after stepping an instruction in the active-not-pending state, EDSCR.STATUS is set to either:

- Halting Step, normal, if the stepped instruction was not a Load-Exclusive instruction.
- Halting Step, exclusive, if the stepped instruction was a Load-Exclusive instruction.

If the stepped instruction was a conditional Load-Exclusive instruction that failed its condition code test, EDSCR.STATUS is set to a CONSTRAINED UNPREDICTABLE choice of Halting Step, normal, or Halting Step, exclusive.

Otherwise the PE enters Debug state without stepping an instruction. This means that the Halting Step state machine enters the active-pending state directly from the inactive state, without going through active-not-pending state. In this case, EDSCR.STATUS is set to Halting Step, no syndrome. This happens when:

- The PE enters directly into the active-pending state on an exception return to Non-secure state from EL3 when Halting is prohibited in Secure state.
- The active-pending state is entered for other reasons. See *Synchronization and the Halting Step state machine on page H3-4742*

In addition, EDSCR.STATUS is set to one of a CONSTRAINED UNPREDICTABLE choice if:

- The instruction being stepped generated a synchronous exception, or a pending asynchronous exception was taken before the instruction was executed.

  In this case EDSCR.STATUS is set to a CONSTRAINED UNPREDICTABLE choice of:

  — Halting Step, no syndrome, or Halting Step, normal, if the stepped instruction was not a Load-Exclusive instruction.

  — Halting Step, no syndrome, or Halting Step, exclusive, if the stepped instruction was a Load-Exclusive instruction.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- The instruction that was stepped was an exception return instruction or an `ISB`. As these instructions are not in the Load-Exclusive instructions, EDSCR.STATUS is set to a CONSTRAINED UNPREDICTABLE choice of Halting Step, no syndrome or Halting Step, normal.
- The PE enters directly into the active-pending state on reset because EDECR.SS is set to 1. EDSCR.STATUS is set to a CONSTRAINED UNPREDICTABLE choice of Halting Step, no syndrome or Halting Step, normal.

In all cases, if EDSCR.STATUS is not set to Halting Step, no syndrome, then it must indicate whether the stepped instruction was a Load-Exclusive instruction by setting EDSCR.STATUS to Halting Step, normal or Halting Step, exclusive.

Note

In an implementation that always sets EDSCR.STATUS to Halting Step, no syndrome is not compliant.

H3.2.9 Pseudocode description of Halting Step debug events

There are two pseudocode functions for Halting Step debug events:

- `RunHaltingStep()`. This is called after an instruction has executed and any exception generated by the instruction is taken. It is also called after taking a reset before executing any instructions. That is, reset is treated like an asynchronous exception, even if EDECR.RCE == 1. `RunHaltingStep()` affects the next instruction.
- `CheckHaltingStep()`. This is called before the next instruction is executed. If a step is pending, it generates the debug event.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H3.3 Halt Instruction debug event

A Halt Instruction debug event is generated when EDSCR.HDE == 1, halting is allowed, and software executes the Halting software breakpoint instruction, HLT.

The pseudocode for Halt Instruction Debug events is described in *HLT* on page C6-524 for A64 and *HLT* on page F5-2587 for A32 and T32.

HLT never generates a debug exception. It is treated as UNDEFINED if EDSCR.HDE == 0, or if halting is prohibited.

Note

A debugger can replace a program instruction with a Halt instruction to generate a Halting Software Breakpoint. Debuggers that use the HLT instruction must be aware of the ARMv8-A rules for concurrent modification of executable code, CMODX. The rules for concurrent modification and execution of instructions do not allow one thread of execution or an external debugger to replace an instruction with an HLT instruction when these same instructions are being executed by a different thread of execution. See *Concurrent modification and execution of instructions* on page B2-82.

The T32 HLT instruction is unconditionally executed inside an IT block, even when it is treated as UNDEFINED. The A32 HLT instruction is CONSTRAINED UNPREDICTABLE if the condition code field is not 0b1110, with the set of behaviors the same as for BKPT. See Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Note

The HLT instruction is part of the external debug solution for ARMv8-A. As such, the presence of the HLT instruction is not indicated in the ID registers. In particular, the AArch32 CP15 register ID_ISAR0. Debug does not indicate the presence of the HLT instruction.

H3.3.1 HLT instructions as the first instruction in a T32 IT block

In an implementation that supports the ITD control, the architecture permits a combination of one T32 IT instruction and certain other 16-bit T32 instruction to be treated as a single 32-bit instruction when the value of the ITD field that applies to the current Exception level is 1.

The T32 HLT instruction cannot be combined with an IT instruction in this way. In an implementation that supports the ITD control, if the first instruction in an IT block is an HLT instruction, then the behavior of the instruction depends on the value of the applicable ITD field:

- If the value of the ITD field is 1, then the combination is treated as UNDEFINED and an Undefined Instruction exception is generated either by the IT instruction or by the HLT instruction.
- If the value of the ITD field is 0, then the HLT instruction either:
  - Is treated as UNDEFINED and generates an Undefined Instruction exception.
  - Generates an HLT Instruction debug event.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0.

To set an HLT Instruction debug event on the first instruction of an IT block, debuggers must replace the IT instruction with an HLT instruction to ensure consistent behavior.

The ITD control fields are:

HSCTLR.ITD Applies to execution at EL2 when EL2 is using AArch32.

SCTLR.ITD Applies to execution at EL0 or EL1 when EL1 is using AArch32.

SCTLR_EL1.ITD
Applies to execution at EL0 using AArch32 when EL1 is using AArch64.

Note

An HLT instruction is always unconditional, even within an IT block.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H3.4 Exception Catch debug event

Exception Catch debug events:

- Are generated when the corresponding bit in the Exception Catch Control Register, EDECCR, is set to 1 on all entries to a given Exception level. This means:
  - Exceptions taken to the Exception level.
  - Exception returns to the Exception level.
  - Entry to the Exception level due to reset. This is an overlap with a Reset Catch debug event. See *Reset Catch debug events* on page H3-4752.
- Are taken synchronously, after entry to the Exception level.
- Ignore the Execution state of the target Exception level.
- Are ignored if halting is prohibited.

The EDECCR contains two fields:

- One field for Non-secure state.
- One field for Secure state.

Each field contains one bit for each Exception level in that state. Bits corresponding to Exception levels that are not implemented are RES0. See *EDECCR, External Debug Exception Catch Control Register* on page H9-4874.

Note

- EDECCR does not replace DBGVCR:
  - DBGVCR is retained in AArch32 state for backwards compatibility.
  - DBGVCR is ignored in AArch64 state and never generates entries to Debug state.
  - DBGVCR cannot be accessed by the external debug interface.
- EDECCR is only visible as OSECCR_EL1 by System Register instructions in AArch64 state, and as DBGOSECCR by CP14 register access instructions in AArch32 state, when the OS Lock is locked to allow software to save and restore it over a powerdown.
- Exception Catch debug events are not disabled when the OS Lock is locked.

For an Exception Catch debug event generated after taking an exception to a trapped Exception level:

- The PE must not fetch instructions from the vector address before entering Debug state, if address translation is disabled in the translation regime at the target Exception level.
- On entering Debug state:
  - The current Exception level is the target Exception level of the exception.
  - The ELR, SPSR, ESR, and other syndrome registers contain information about the exception.
  - DLR contains the exception vector address.

H3.4.1 Prioritization of Exception Catch debug events

The following rules define the prioritization of Exception Catch debug events:

- It is IMPLEMENTATION DEFINED whether Exception Catch debug events are higher or lower priority than each of Software Step exceptions and Halting Step debug events.
- Exception Catch debug events are higher priority than all synchronous exceptions other than Software Step exceptions.
- Exception Catch debug events are lower priority than Reset Catch debug events.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Note

As described in *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1478, an exception trapping form of a Vector Catch debug event might generate a second debug exception as part of the exception entry, before the Exception Catch debug event is taken. See *Vector Catch exceptions* on page D2-1597 or *Vector Catch exceptions* on page G2-3829.

A second unmasked asynchronous exception can be taken before the PE enters Debug state. If this second exception does not generate an Exception Catch debug event, the exception handler executed at the higher Exception level later returns to the trapped Exception level, causing the Exception Catch debug event to be generated again.

See also *Debug state entry and debug event prioritization* on page H2-4697.

H3.4.2 CONSTRAINED UNPREDICTABLE generation of Exception Catch debug events

When the PE is executing code at a given Exception level and the corresponding EDECCR bit is 1, it is CONSTRAINED UNPREDICTABLE whether an Exception Catch debug event is generated.

Note

It is possible to generate Exception Catch debug events:

- As a trap on all instruction fetches from the trapped Exception level as part of an instruction fetch.
- On entry to the Exception level, as described in *Detailed Halting Step state machine behavior* on page H3-4739.

This is similar to the implementation options allowed for Vector Catch debug events. The architecture does not require that the event is generated following an `ISB` operation executed at the Exception level.

Examples of this are:

- If the debugger writes to EDECCR so that the current Exception level is trapped.
- If the OS restore code writes to OSECCR so that the current Exception level is trapped.
- If the code executing in AArch32 state changes the Exception level or security state other than by an exception return, and the target Exception level is trapped. See *State and mode changes without explicit context synchronization operations* on page G2-3838.

H3.4.3 Examples of Exception Catch debug events

If EDECCR == `0x20`, meaning that the Exception Catch debug event is enabled for Non-secure EL1, then the following exceptions generate Exception Catch debug events:

- An exception taken from Non-secure EL0 to Non-secure EL1.
- An exception return from EL2 to Non-secure EL1.
- An exception return from EL3 to Non-secure EL1.

For example, on taking a Data Abort exception from Non-secure EL0 to Non-secure EL1, using AArch64:

- ELR_EL1 and SPSR_EL1 are written with the preferred return address and PE state for a return to EL0.
- ESR_EL1 and FAR_EL1 are written with the syndrome information for the exception.
- DLR_EL0 is set to VBAR_EL1 + `0x400`, the synchronous exception vector.
- DSPSR_EL0 is written with the PE state for an exit to EL1.

The following do not generate Exception Catch debug events:

- An exception taken from Non-secure EL0 to EL2 or EL3.
- An exception return from EL2 to Non-secure EL0.
- An exception taken from Secure EL0 to Secure EL1.
- An exception return from EL3 to Secure EL1.

H3.4.4 Pseudocode description of Exception Catch debug events

The pseudocode function `CheckExceptionCatch()` is described in Chapter J1 *ARMv8 Pseudocode*.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H3.5 External Debug Request debug event

External Debug Request debug events are asynchronous debug events.

An External Debug Request debug event is generated when signaled by the embedded cross-trigger. See Chapter H5 *The Embedded Cross-Trigger Interface*.

Note

ARMv8-A requires the implementation of an embedded cross-trigger.

An implementation might also support IMPLEMENTATION DEFINED ways of generating an External Debug Request debug event.

If an External Debug Request debug event is being asserted at the point where a reset is taken, then the PE enters Debug state before it completes execution of the first instruction following the reset, provided that the state into which the PE resets allows halting.

H3.5.1 Pseudocode description of External Debug Request debug events

The `ExternalDebugRequest()` function is described in Chapter J1 *ARMv8 Pseudocode*.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H3.6 OS Unlock Catch debug event

An OS Unlock Catch debug event is generated when EDECR.OSUCE == 1 and the state of the OS Lock changes from locked to unlocked.

When the OS Unlock Catch debug event is generated, it is recorded by setting EDESR.OSUC to 1, meaning it immediately becomes pending. However, it is not guaranteed to be taken immediately. See *Synchronization and Halting debug events* on page H3-4754.

OS Unlock Catch debug events are not generated if the OS Lock is unlocked when the PE is in Debug state. See also:

- *Debug behavior when the OS Lock is unlocked* on page H6-4800.
- *EDECR, External Debug Execution Control Register* on page H9-4876.
- *EDESR, External Debug Event Status Register* on page H9-4878.

EDESR.OSUC is cleared to 0 on a Warm reset and on exiting Debug state.

H3.6.1 Using the OS Unlock Catch debug event

If the debugger attempts to access a debug register when the Core power down domain is completely off or in a low-power state in which the core power domain registers cannot be accessed, and that access returns an error, then the debugger must retry the access. However, if the Core power domain is regularly powered down, this can lead to unreliable debugger behavior.

The debugger can program a Reset Catch debug event to halt the PE when it has powered up, and can program the debug registers from Debug state. However, if the PE boot software restores the debug registers, as described in *Debug OS Save and Restore sequences* on page H6-4798, then newly written values are overwritten by the restore sequence.

The debugger can program an OS Unlock Catch debug event to halt the PE after the restore sequence has completed, and program the debug registers from Debug state.

H3.6.2 Pseudocode description of OS Unlock Catch debug event

The `CheckOSUnlockCatch()` function is called when the OS Lock is unlocked.

The `CheckPendingOSUnlockCatch()` function is called before an instruction is executed. If an OS Unlock Catch is pending, it generates the debug event.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H3.7 Reset Catch debug events

A Reset Catch debug event is generated when EDECR.RCE == 1 and the PE exits reset state. When the Reset Catch debug event is generated, it is recorded by setting EDESR.RC to 1.

If halting is allowed when the event is generated, the Reset Catch debug event is taken immediately and synchronously. On entering Debug state, DLR has the address of the reset vector. The PE must not fetch any instructions from memory.

Otherwise, the Reset Catch debug event is pended and taken when halting is allowed. See also:

- *Synchronization and Halting debug events* on page H3-4754.
- *EDECR, External Debug Execution Control Register* on page H9-4876.
- *EDESR, External Debug Event Status Register* on page H9-4878.

This means that EDESR.RC is set to the value of EDECR.RCE on a Warm reset. EDESR.RC is cleared to 0 on exiting Debug state.

H3.7.1 Pseudocode description of Reset Catch debug event

The `CheckResetCatch()` function is called after reset before executing any instruction.

The `CheckPendingResetCatch()` function is called before an instruction is executed. If a Reset Catch is pending, it generates the Reset Catch debug event.

Non-Confidential - Beta

H3.8 Software Access debug event

When the value of EDSCR.TDA == 1, software access to the following debug AArch64 System registers and AArch32 CP14 registers cause a trap to Debug state:

- The Breakpoint Value Registers, DBGBVR.
- The Breakpoint Control Registers, DBGBCR.
- The Watchpoint Value Registers, DBGWVR.
- The Watchpoint Control Registers, DBGWCR.

However, EDSCR.TDA is ignored if one of:

- The value of OSLSR.OSLK == 1, meaning that the OS Lock is locked.
- Halting is prohibited. See *Halting allowed and halting prohibited* on page H2-4695.
- The register access generates an exception.

Note

- DBGPRCR.CORENPDRQ (Core No-powerdown Request), DCC registers, and CLAIM tag bits are also shared, but are deliberately excluded from this list.
- Only accesses as System registers in AArch64 state or CP14 registers in AArch32 state generate a trap. Accesses to the memory-mapped interface by a PE are not trapped.

H3.8.1 Pseudocode description of Software Access debug event

The `CheckSoftwareAccessToDebugRegisters()` function is described in Chapter J1 *ARMv8 Pseudocode*.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H3.9 Synchronization and Halting debug events

The behavior of external debug depends on:

- Indirect reads of:
  - External debug registers.
  - System registers, including system debug registers.
  - Special-purpose registers.
- The state of the external authentication interface.

This means that any change to these registers or the external authentication interface requires explicit synchronization by a *Context synchronization operation* before the change takes effect. This ensures that for instructions appearing in program order after the change, the change affects the following:

- The generation and behavior of Software debug events. See *Synchronization and debug exceptions* on page D2-1612 for exceptions taken from AArch64 state, or *Synchronization and debug exceptions* on page G2-3837 for exceptions taken from AArch32 state.
- The generation of all Halting debug events.
- Taking a pending Halting debug event or other asynchronous Debug event. See:
  - *Pending Halting debug events*.
  - *Taking Halting debug events asynchronously* on page H3-4755.
- The behavior of the Halting Step state machine. See *Synchronization and the Halting Step state machine* on page H3-4742.

If there is an instruction between the change and the *Context synchronization operation*, it is CONSTRAINED UNPREDICTABLE whether the PE uses the old state or the new state.

For some registers, all read and write accesses that update the register occur in program order, without any additional synchronization, but others require an explicit *Context synchronization operation*. For more information on the synchronization of register updates see:

- *Synchronization requirements for AArch64 System registers* on page D7-1802.
- *Synchronization of changes to the external debug registers* on page H8-4812.
- *State and mode changes without explicit context synchronization operations* on page G2-3838.

A change on the external authentication interface is typically asynchronous to software and can happen without a *Context synchronization operation*.

External Debug Request debug events must be taken in finite time, without requiring the synchronization of any necessary change to the external authentication interface.

Example H3-3 shows an example of the synchronization requirements.

Example H3-3 Synchronization requirements

Secure software locks up in a tight loop, so it executes indefinitely without any synchronization operations. An External debug request must be able to break the PE out of that loop. This is a requirement even if **DBGEN** or **SPIDEN** or both are LOW on entry to the loop, meaning that halting is prohibited, and are only asserted HIGH later.

H3.9.1 Pending Halting debug events

A pending Halting debug event is taken when halting becomes allowed. This can happen without a *Context synchronization operation* if:

- The PE enters Non-secure state with `ExternalInvasiveDebugEnabled()` == TRUE, and this is not the result of an exception return. See *State and mode changes without explicit context synchronization operations* on page G2-3838.
- A change on the external authentication interface means halting becomes allowed in the current state.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- The OS Double Lock status, `DoubleLockStatus()` becomes FALSE. For example, this can happen when software clears OSDLR.DLK to 0 or sets DBGPRCR.COREPDRQ to 1.
- The debug event is an OS Unlock Catch debug event. OS Unlock Catch debug events are generated in a pending state, rather than taken synchronously.

In these cases a pending Halting debug event is taken asynchronously.

H3.9.2 Taking Halting debug events asynchronously

The ARM architecture does not define when Halting debug events that are taken asynchronously are taken.

Any Halting debug event that is observed as pending in the EDESR before a *Context synchronization operation*, or an External Debug Request debug event that is asserted before a *Context synchronization operation*, is taken and the PE enters Debug state before the first instruction following the *Context synchronization operation* completes its execution. This is only possible if halting is allowed after completion of the *Context synchronization operation*.

If the first instruction after the *Context synchronization operation* generates a synchronous exception, or an asynchronous exception is also pending, then the architecture does not define the order in which the debug event and the exception or exceptions are taken, unless both:

- A Halting Step debug event is pending. EDESR.SS == 1.
- The *Context synchronization operation* is an exception return from a state where halting is prohibited to a state where halting is allowed.

Note

This applies to an exception return from Secure state with `ExternalSecureInvasiveDebugEnabled()` == FALSE to Non-secure state with `ExternalInvasiveDebugEnabled()` == TRUE.

In this case the order in which the debug events are handled is specified to avoid a double-step. See *Entering the active-pending state* on page H3-4741.

An External Debug Request debug event that is being asserted when the PE comes out of reset is taken, and the PE enters Debug state before the first instruction after the reset completes its execution, provided that halting is allowed when the PE exits reset state

Note

These rules are based on the rules that apply to taking asynchronous exceptions. See *Asynchronous exception types, routing, masking and priorities* on page D1-1485.

Chapter H4
The Debug Communication Channel and Instruction Transfer Register

This chapter describes communication between a debugger and the implemented debug logic, using the *Debug Communications Channel* (DCC) and the *Instruction Transfer Register* (ITR), and associated control flags. It contains the following sections:

- *Introduction* on page H4-4758.
- *DCC and ITR registers* on page H4-4759.
- *DCC and ITR access modes* on page H4-4761.
- *Flow control of the DCC and ITR registers* on page H4-4765.
- *Synchronization of DCC and ITR accesses* on page H4-4768.
- *Interrupt-driven use of the DCC* on page H4-4773.
- *Pseudocode description of the operation of the DCC and ITR registers* on page H4-4774.

Note

Where necessary Table K13-1 on page K13-5568 disambiguates the general register references used in this chapter.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H4.1 Introduction

The *Debug Communications Channe*l, DCC, is a channel for passing data between the PE and an external agent, such as a debugger. The DCC provides a communications channel between:

- An external debugger, described as the *debug host*.
- The debug implementation on the PE, described as the *debug target*.

The DCC can be used:

- As a 32-bit full-duplex channel.
- As a 64-bit half-duplex channel.

The DCC is an essential part of Debug state operation and can also be used in Non-debug state.

The *Instruction Transfer Register*, ITR, passes instructions to the PE to execute in Debug state.

The PE includes flow-control mechanisms for both the DCC and ITR.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H4.2 DCC and ITR registers

The DCC comprises *data transfer registers*, the DTRs, and associated flow-control flags. The data transfer registers are DTRRX and DTRTX.

The ITR comprises a single register, EDITR, and associated flow-control flags.

In AArch64 state, software can access the data transfer registers as:

- A receive and transmit pair for 32-bit full duplex operation:
  - The write-only DBGDTRTX_EL0 register to transmit data.
  - The read-only DBGDTRRX_EL0 register to receive data.
- A single 64-bit read/write register, DBGDTR_EL0, for 64-bit half-duplex operation.
- The read/write OSDTRTX_EL1 and OSDTRRX_EL1 registers for save and restore.

In AArch32 state, software can only access the data transfer registers as:

- A receive and transmit pair, for 32-bit full duplex operation:
  - The write-only DBGDTRTXint register to transmit data.
  - The read-only DBGDTRRXint register to receive data.
- The read/write DBGDTRTXext and DBGDTRRXext registers for save and restore.

The data transfer registers are also accessible by the external debug interface as a pair of 32-bit registers, DBGDTRRX_EL0 and DBGDTRTX_EL0. Both registers are read/write, allowing both 32-bit full-duplex and 64-bit half-duplex operation.

The DCC flow-control flags are EDSCR.{RXfull, TXfull, RXO, TXU}:

- The RXfull and TXfull ready flags are used for flow-control and are visible to software in the debug System registers in DCCSR.
- The RX overrun flag, RXO, and the TX underrun flag, TXU, report flow-control errors.
- The flow-control flags are also accessible by software as simple read/write bits for saving and restoring over a powerdown when the OS Lock is locked in DSCR.
- The flow-control flags are accessible from the external debug interface in EDSCR.

Figure H4-1 on page H4-4760 shows the System register and external debug interface views of the EDSCR and DTR registers in both AArch64 state and AArch32 state. These figures do not include the save and restore views.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

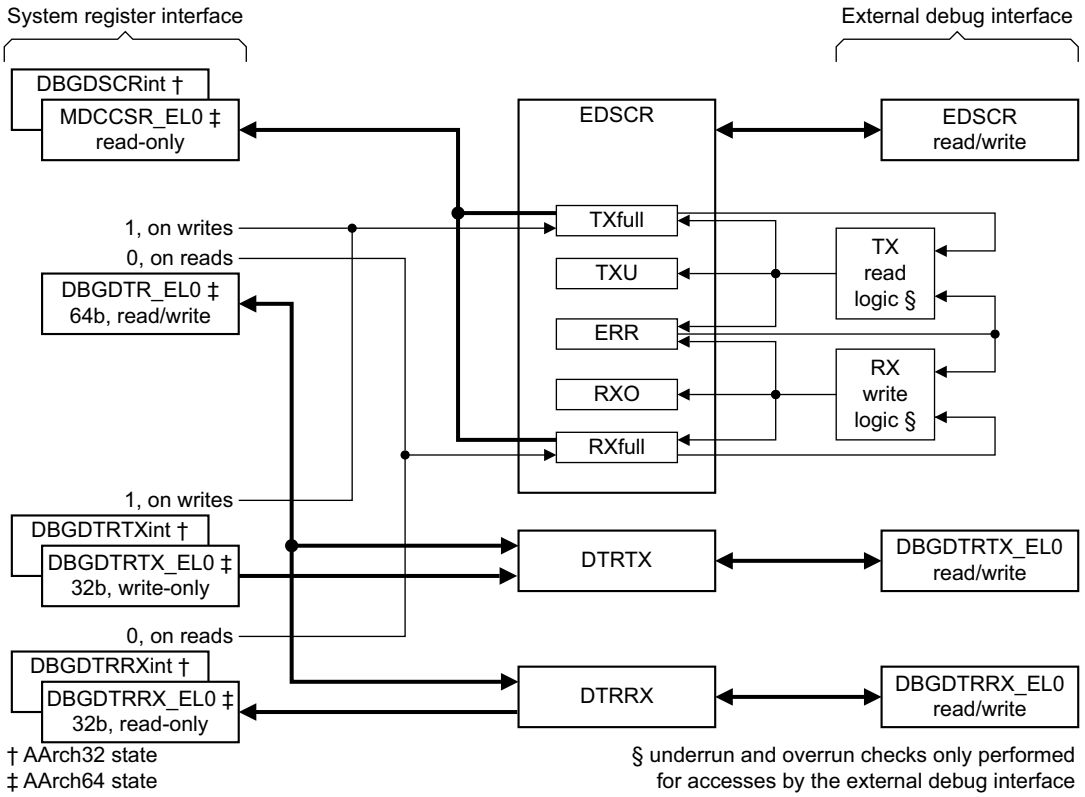

Figure H4-1 System register and external debug interface views of EDSCR and DTR registers, Normal access mode

EDITR and the ITR flow-control flags, EDSCR.{ITE, ITO} are accessible only by the external debug interface:

- The EDITR specifies an instruction to execute in Debug state.
- The ITR empty flag, ITE, is used for flow-control.
- The ITR overrun flag, ITO, reports flow-control errors.

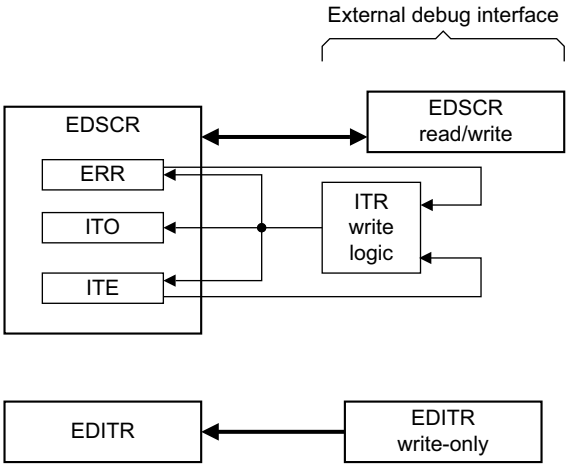

Figure H4-2 External debug interface views of EDSCR and EDITR registers, Normal access mode

The sticky overflow flag, EDSCR.ERR, is used by both the DCC and ITR to report flow-control errors.

Non-Confidential - Beta

H4.3 DCC and ITR access modes

The DCC and ITR support two access modes:

DCC and ITR access mode, links to description	Applies when:
Normal access mode	EDSCR.MA == 0 or the PE is in Non-debug state
Memory access mode on page H4-4762	EDSCR.MA == 1 and the PE is in Debug state

H4.3.1 Normal access mode

The Normal access mode allows use of the DCC as a communications channel between target and host. It also allows the use of the ITR for issuing instructions to the PE in Debug state.

In Normal access mode, if there is no overrun or underrun, the following occurs:

For accesses by software:

- Direct writes to DBGDTRTX update the value in DTRTX and indirectly write 1 to TXfull.
- Direct reads from DBGDTRRX return the value in DTRRX and indirectly write 0 to RXfull.
- In AArch64 state, direct writes to DBGDTR_EL0 update both DTRTX and DTRRX, indirectly write 1 to TXfull, and do not change RXfull:
  - DTRTX is set from bits[31:0] of the transfer register.
  - DTRRX is set from bits[63:32] of the transfer register.
- In AArch64 state, direct reads from DBGDTR_EL0 return the concatenation of DTRRX and DTRTX, indirectly write 0 to RXfull, and do not change TXfull:
  - Bits[31:0] of the transfer register are set from DTRRX.
  - Bits[63:32] of the transfer register are set from DTRTX.

Note

For DBGDTR_EL0, the word order is reversed for reads with respect to writes.

Software reads TXfull and RXfull using DCCSR.

For accesses by the external debug interface:

- Writes to EDITR trigger the instruction to be executed if the PE is in Debug state:
  - If the PE is in AArch64 state, this is an A64 instruction.
  - If the PE is in AArch32 state, this is a T32 instruction. The T32 instruction is a pair of halfwords where the first halfword is taken from the lower 16-bits, and the second halfword is taken from the upper 16-bits.
- Reads of DBGDTRTX_EL0 return the value in DTRTX and indirectly write 0 to TXfull.
- Writes to DBGDTRTX_EL0 update the value in DTRTX and do not change TXfull.
- Reads of DBGDTRRX_EL0 return the value in DTRRX and do not change RXfull.
- Writes to DBGDTRRX_EL0 update the value in DTRRX and indirectly write 1 to RXfull.

TXfull and RXfull are visible to the external debug interface in EDSCR.

The PE detects overrun and underrun by the external debug interface, and records errors in EDSCR.{TXU, RXO, ITO, ERR}. See *Flow control of the DCC and ITR registers* on page H4-4765.

See also *Synchronization of DCC and ITR accesses* on page H4-4768.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H4.3.2 Memory access mode

When the PE is in Debug state, *Memory access mode* can be selected to accelerate word-aligned block reads or writes of memory by an external debugger. Memory access mode can only be enabled in Debug state, and no instructions can be issued directly by the debugger when in Memory access mode.

If there is no overrun or underrun when in Memory access mode, an access by the external debug interface results in the following:

- External reads from DBGDTRTX_EL0 cause:
  1. The existing value in DTRTX to be returned. This clears EDSCR.TXfull to 0.
  2. The equivalent of `LDR W1,[X0],#4`, if in AArch64 state, or `LDR R1,[R0],#4`, if in AArch32 state, to be executed.
  3. The equivalent of the `MSR DBGDTRTX_EL0,X1` instruction, if in AArch64 state, or the `MCR p14,0,R1,c0,c5,0` instruction, if in AArch32 state, to be executed.
  4. EDSCR.{TXfull, ITE} to be set to {1,1}, and X1 or R1 to be set to an UNKNOWN value.
- External writes to DBGDTRRX_EL0 cause:
  1. The value in DTRRX to be updated. This sets EDSCR.RXfull to 1.
  2. The equivalent of the instruction `MRS X1,DBGDTRRX_EL0`, if in AArch64 state, or `MRC p14,0,R1,c0,c5,0` if in AArch32 state, to be executed.
  3. The equivalent of the instruction `STR W1,[X0],#4`, if in AArch64 state, or `STR R1,[R0],#4`, if in AArch32 state, to be executed.
  4. EDSCR.{RXfull, ITE} to be set to {0,1}, and X1 or R1 to be set to an UNKNOWN value.
- External reads from DBGDTRRX_EL0 return the last value written to DTRRX.
- External writes to EDITR generate an overrun error.

During these accesses, EDSCR.{TXfull, RXfull, ITE} are used for flow control.

The architecture does not require precisely when these flags are set or cleared by the sequence of operations outlined in this section. For example, in the case of an external write to DBGDTRRX_EL0, in AArch64 state, RXfull might be cleared after step 2, or it might not be cleared until after step 3, as an implementation is free to fuse these steps into a single operation. The architecture does require that the flags are set as at step 4 when the PE is ready to accept a further read or write without causing an overrun error or an underrun error.

The process outlined in this section represents a simple sequential execution model of Memory access mode. An implementation is free to pipeline, buffer, and re-order instructions and transactions, as long as the following remain true:

- Data items are transferred into and out of the DTR in order and without loss of data, other than as a result of an overrun or an underrun.
- Data Aborts occur in order.
- The constraints of the memory type are met.
- In the list describing *External reads from DBGDTRTX_EL0*:
  - The `MSR` equivalent operation at step 3 of the sequence reads the value loaded by step 2.
  - If the list is performed in a loop, for all but the first iteration of this list, the value read by step 1 returns the values written by the `MSR` equivalent operation at the previous iteration of step 3.
- In the list describing *External writes to DBGDTRRX_EL0*:
  - The `MRS` equivalent operation at step 2 of the sequence returns the value written at step 1.
  - The `STR` equivalent at step 3 of the sequence writes the value read at step 2.
- If the PE cannot accept a read or write, as applicable, during the sequence, then the flags are updated to indicate an overrun or underrun

See *Flow control of the DCC and ITR registers* on page H4-4765 for more information on overrun and underrun.

Non-Confidential - Beta

Ordering, access sizes and effect on exclusive monitors

For the purposes of memory ordering, access sizes, and effect on the exclusive monitor, accesses in Memory access mode are consistent with Load/Store word instructions executed by the PE.

Data Aborts in Memory access mode

If a memory access generates a Data Abort, then:

- The Data Abort exception is taken. See *Exceptions in Debug state* on page H2-4724:
  - This means EDSCR.ERR is set to 1, see *Cumulative error flag* on page H4-4767.
  - If the Data Abort occurs on stage 2 of an address translation, then the values returned in the ISV field and in bits[23:14] of the ISS are UNKNOWN.

    If this Data Abort is taken to EL2 using AArch64, the ISS is returned by ESR_EL2. *ISS encoding for an exception from a Data Abort* on page D7-1870 describes the usual encoding of this ISS.

    If EL2 is using AArch32 and this Data Abort is taken to Hyp mode, the ISS is returned by HSR. *ISS encoding for an exception from a Data Abort* on page G6-4264 describes the usual encoding of this ISS.
- Register R0 retains the address that generated the abort.
- Register R1 is set to an UNKNOWN value.
- EDSCR.TXfull, for a load, or EDSCR.RXfull, for a store, is set to an UNKNOWN value.
- DTRTX, for a load, or DTRRX, for a store, is set to an UNKNOWN value.
- EDSCR.ITE is set to 1.

Illegal Execution state exception

If PSTATE.IL is set to 1 when EDSCR.MA == 1, then on an external write access to DBGDTRRX_EL0 or an external read from DBGDTRTX_EL0, it is CONSTRAINED UNPREDICTABLE whether the PE:

- Takes an Illegal Execution state exception without performing any operations. In this case:
  - EDSCR.ERR is set to 1, see *Cumulative error flag* on page H4-4767.
  - Register R0 is unchanged.
  - Register R1 is set to an UNKNOWN value.
  - EDSCR.TXfull or EDSCR.RXfull, as applicable, is set to an UNKNOWN value.
  - DTRTX or DTRRX, as applicable, is set an UNKNOWN value.
  - EDSCR.ITE is set to 1.

  See also *Exceptions in Debug state* on page H2-4724.
- Ignores PSTATE.IL.

Note

The typical usage model for Memory access mode involves executing instructions in Normal access mode to set up X0 before setting EDSCR.MA to 1. These instructions generate an Illegal state exception if PSTATE.IL is set to 1.

Alignment constraints

If the address in R0 is not aligned to a multiple of four, the behavior is as follows:

- For each external DTR access a CONSTRAINED UNPREDICTABLE choice of:
  1. The PE makes an unaligned memory access to R0. If alignment checking is enabled for the memory access, this generates an Alignment fault.
  2. The PE makes a memory access to `Align(X[0],4)` in AArch64 state, or `Align(R[0],4)` in AArch32 state.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

3. The PE generates an Alignment fault, regardless of whether alignment checking is enabled.
4. The PE does nothing.

- Following each memory access, if there is no Data Abort, R0 is updated with an UNKNOWN value.
- For external writes to DBGDTRRX_EL0, if the PE writes to memory, an UNKNOWN value is written.
- For external reads of DBGDTRTX_EL0 an UNKNOWN value is returned.
- The RXfull and TXfull flags are left in an UNKNOWN state, meaning that a DBGDTRTX_EL0 read can trigger a TX underrun, and a DBGDTRTX_EL0 write can trigger an RX overrun.

H4.3.3 Memory-mapped accesses to the DCC and ITR

Writes to the flags in EDSCR by external debug interface accesses to the DCC and the ITR registers are indirect writes, because they are a side-effect of the access. The indirect write might not occur for a memory-mapped access to the external debug interface. For more information, see *Register access permissions for memory-mapped accesses* on page H8-4816.

Non-Confidential - Beta

H4.4 Flow control of the DCC and ITR registers

This sub-section describes the flow-control of the DCC and ITR registers:

- *Ready flags*.
- *Buffering writes to EDITR*.
- *Overrun and underrun flags* on page H4-4766.
- *Cumulative error flag* on page H4-4767.

H4.4.1 Ready flags

In Normal access mode:

- For the DTR registers there are two ready flags:
  - EDSCR.RXfull == 1 indicates that DBGDTRRX_EL0 contains a valid value that has been written by the external debugger and not yet read by software running on the target.
  - EDSCR.TXfull == 1 indicates that DBGDTRTX_EL0 contains a valid value that has been written by software running on the target and not yet read by an external debugger.
- For the ITR register there is a single ready flag:
  - EDSCR.ITE == 1 indicates that the PE is ready to accept an instruction to the ITR.

    Note

    The architecture permits a PE to continue to accept and buffer instructions when previous instructions have not completed their architecturally defined behavior, as long as those instructions are discarded if EDSCR.ERR is set, either by an underrun or overrun or by any of the other error conditions described in this architecture, such as an instruction generating an abort.

In Memory access mode:

- EDSCR.{RXfull, ITE} == {0,1} indicates that DBGDTRRX_EL0 is empty and the PE is ready to accept a word external write to DBGDTRRX_EL0.
- EDSCR.{TXfull, ITE} == {1,1} indicates that DBGDTRTX_EL0 is full and the PE is ready to accept a word external read from DBGDTRTX_EL0.

All other values indicate that the PE is not ready, and result in a DTR overrun or underrun error, an ITR overrun error, or both, as defined in *Overrun and underrun flags* on page H4-4766.

EDSCR.{ITE, RXfull, TXfull} shows the status of the ITR and DCC registers. It ignores the question of whether a read or write cannot be accepted because, for example, EDSCR.ERR is set or the software lock is locked for memory-mapped accesses (EDLSR.SLK == 1).

H4.4.2 Buffering writes to EDITR

The architecture permits a processor to continue to accept and buffer instructions when previous instructions have not completed their architecturally defined behavior, provided that:

- Those instructions are discarded if EDSCR.ERR is set to 1, either by an underrun or an overrun, or by any other error conditions described in this architecture, such as an instruction generating an abort.
- The PE maintains the simple sequential execution model with the order of instructions determined by the order in which the PE accepts the EDITR writes. In particular, the buffered instructions must be executed in the Execution state consistent with a simple sequential execution of the instructions, even if one of the previous instructions is a state changing operation, such as `DCPS` or `DRPS`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H4.4.3 Overrun and underrun flags

Each of the ready flags has a corresponding overrun or a corresponding underrun flag. These are sticky status flags that are set if the register is accessed using the external debug interface when the corresponding ready flag is not in the ready state.

If the PE is in Debug state and Memory access mode, the corresponding error flag is also set if the PE is not ready to accept an operation because a previous load or store is still in progress. The sticky status flag remains set until cleared by writing 1 to EDRCR.CSE.

Note

The architecture permits a PE to continue to accept and buffer data to write to memory in Memory access mode.

Table H4-1 shows DCC and ITR ready flags and the overrun and underrun flags associated with them.

Table H4-1 DCC and ITR ready flags and the associated overrun/underrun flags

External debug interface access	Overrun/Underrun condition	EDSCR flag
Write DBGDTRRX_EL0	`EDSCR.RXfull == '1' || (Halted() && EDSCR.MA == '1' && EDSCR.ITE == '0')`	RXO
Read DBGDTRTX_EL0	`EDSCR.TXfull == '0' || (Halted() && EDSCR.MA == '1' && EDSCR.ITE == '0')`	TXU
Write EDITR	`Halted() && (EDSCR.ITE == '0' || EDSCR.MA == '1')`	ITO

When an overrun or underrun flag is set to 1, the cumulative error flag, EDSCR.ERR, described in *Cumulative error flag* on page H4-4767, is also set to 1.

In the event of an external write to DBGDTRRX_EL0 or EDITR generating an overrun, or an external read from DBGDTRTX_EL0 generating an underrun:

- For a write, the written value is ignored.
- For a read, an UNKNOWN value is returned.
- EDSCR.TXfull, EDSCR.RXfull or EDSCR.ITE, as applicable, are not updated.

There is no overrun or underrun detection on external reads of DBGDTRRX_EL0 or external writes of DBGDTRTX_EL0.

There is no overrun or underrun detection of direct reads and direct writes of the DTR System registers by software:

- If RXfull == 0, a direct read of DBGDTRRX or DBGDTR_EL0 returns UNKNOWN.
- If TXfull == 1, a direct write of:
  - DBGDTRTX sets DTRTX to UNKNOWN.
  - DBGDTR_EL0 sets DTRRX and DTRTX to UNKNOWN.

See *DCC accesses in Non-debug state* on page H4-4769 for more information.

Accessing 64-bit data

In AArch64 state, a software access to the DBGDTR_EL0 register and an external debugger access to both DBGDTRRX_EL0 and DBGDTRTX_EL0 can perform a 64-bit half-duplex operation.

However, there is only overrun and underrun detection on one of the external debug registers. That is:

- If software directly writes a 64-bit value to DBGDTR_EL0, only TXfull is set to 1, meaning:
  - A subsequent external write to DBGDTRRX_EL0 would not be detected as an overrun.
  - If the external debugger reads DBGDTRTX_EL0 first, software might observe MDCCSR_EL0.TXfull == 0 and send a second value before the external debugger reads DBGDTRRX_EL0, leading to an undetected overrun.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- On external writes to both DBGDTRRX_EL0 and DBGDTRTX_EL0 only RXfull is set to 1, meaning:
  - A subsequent direct write of DBGDTRTX_EL0 would not be detected as an overrun.
  - If the external debugger writes to DBGDTRRX_EL0 first, software might observe MDCCSR_EL0.RXfull == 1 and read a full 64-bit value, before the external debugger writes to DBGDTRTX_EL0, leading to an undetected underrun.

To avoid this, debuggers need to be aware of the data size used by software for transfers and ensure that 64-bit data is read or written in the correct order. If the PE is in Non-debug state, this order is as follows:

- The external debugger must check EDSCR.{RXfull, TXfull} before each transfer.
- To receive a 64-bit value from the target, the external debugger must read DBGDTRRX_EL0 before reading DBGDTRTX_EL0.
- To send a 64-bit value to the target, the external debugger must write to DBGDTRTX_EL0 before writing DBGDTRRX_EL0.

Because three accesses are required to transfer 64 bits of data, 64-bit transfers are not recommended for regular communication between host and target. The use of underrun and overrun detection means that only one access is required for 32 bits of data when using 32-bit transfers.

In Debug state, the debugger controls the instructions executed by the PE, so these limitations do not apply. 64-bit transfers provide a means to transfer a 64-bit general register between the host and the target in Debug state.

H4.4.4 Cumulative error flag

The cumulative error flag, EDSCR.ERR, is set to 1:

- On taking an exception from Debug state.
- On any signaled overrun or underrun in the DCC or ITR.

When EDSCR.ERR == 1:

- External reads of DBGDTRTX_EL0 do not have any side-effects.
- External writes to DBGDTRRX_EL0 are ignored.
- External writes to EDITR are ignored.
- No further instructions can be issued in Debug state. This includes any instructions previously accepted as external writes to EDITR that occur in program order after the instruction or access that caused the error.

This allows a debugger to stream data, or, in Debug state, instructions, to the target without having to:

- Check EDSCR.{RXfull, TXfull, ITE} before each access.
- Check EDSCR.{ITO, RXO, TXU} following each access, for overrun or underrun.
- Check PSTATE or other syndrome registers, or both, for an exception following each instruction executed in Debug state that might generate a synchronous exception.

The cumulative error flag remains set until cleared by writing 1 to EDRCR.CSE. See *EDRCR, External Debug Reserve Control Register* on page H9-4906.

For overruns and underruns, EDSCR.{ITO, RXO, TXU} record the error type.

Pseudocode description of clearing the error flag

The `ClearStickyErrors()` pseudocode function is described in Chapter J1 *ARMv8 Pseudocode*.

H4.5 Synchronization of DCC and ITR accesses

In addition to the standard synchronization requirements for register accesses, the following subsections describe additional requirements that apply for the DCC and ITR registers:

- *Summary of System register accesses to the DCC*.
- *DCC accesses in Non-debug state* on page H4-4769.

In these sections, accesses by the external debug interface are referred to as external reads and external writes. Accesses to System registers are referred to as direct reads, direct writes, indirect reads, and indirect writes.

Note

In *Synchronization requirements for AArch64 System registers* on page D7-1802 external reads and external writes are described as forms of indirect access. This whole section uses more explicit terminology.

The DTR registers and the DCC flags, TXfull and RXfull, form a communication channel, with one end operating asynchronously to the other. Implementations must respect the ordering of accesses to these registers in order to maintain the correct behavior of the channel.

External reads of, and external writes to DBGDTRRX_EL0 and DBGDTRTX_EL0 are asynchronous to direct reads of, and direct writes to, DBGDTRRX, DBGDTRTX, and in AArch64 state DBGDTR_EL0, made by software using System register access instructions. The direct reads and direct writes indirectly write to the DCC flags. The external reads and external writes indirectly read the DCC flags to check for underrun and overrun.

Throughout this section:

DCC flags Means any or all of the following:
- The EDSCR.{RXfull.TXfull} ready flags.
- The EDSCR.RXO overrun flag.
- The EDSCR.TXU underrun flag.
- The EDSCR.ERR cumulative error flag.

ITR flags Means any or all of the following:
- The EDSCR.ITE ready flag.
- The EDSCR.ITO overrun flag.
- The EDSCR.ERR cumulative error flag.

H4.5.1 Summary of System register accesses to the DCC

System register accesses to the DTR registers are direct reads and writes of those registers, as shown in Table H4-2 on page H4-4769. Several of these instructions access the same registers using different encodings.

With the exception of the read and write bits, DBGDTRRX and DBGDTRTX are the same encoding, with exception of the read/write bits, but use different registers. The ARMv8 architecture governs the order of these instructions, as described in *Synchronization requirements for AArch64 System registers* on page D7-1802. For more details, see the description of the individual register in the relevant chapter, Chapter D7 *AArch64 System Register Descriptions* or Chapter G6 *AArch32 System Register Descriptions*.

Table H4-2 on page H4-4769 shows a summary of System register accesses to the DCC.

Table H4-2 Summary of System register accesses to the DCC

Operation	OS Lock	AArch64 (MRS/MSR)	AArch32 (MRC/MCR)	Description
Read	-	DBGDTRRX_EL0	DBGDTRRXint	Direct read of DTRRX Indirect write to the DCC flags
Write	-	DBGDTRTX_EL0	DBGDTRTXint	Direct read of DTRTX Indirect write to the DCC flags
Read/write	-	DBGDTR_EL0	-	Direct read/write of both DTRRX and DTRTX Indirect write to the DCC flags
Read	-	MDCCSR_EL0	DBGDSCRint	Direct read of the DCC flags
Read/write	-	OSDTRRX_EL1	DBGDTRRXext	Direct read/write of DTRRX
Read/write	-	OSDTRTX_EL1	DBGDTRTXext	Direct read/write of DTRTX
Read	Unlocked	MDSCR_EL1	DBGDSCRext	Direct read of DCC flags
Read/write	Locked	MDSCR_EL1	DBGDSCRext	Direct read/write of DCC flags

H4.5.2 DCC accesses in Non-debug state

In Non-debug state DCC accesses are as described in *Normal access mode* on page H4-4761:

- If a direct read of DCCSR returns RXfull == 1, then a following direct read of DBGDTRRX, or in AArch64 state of DBGDTR_EL0, returns valid data and indirectly writes 0 to DCCSR.RXfull as a side-effect.
- If a direct read of DCCSR returns TXfull == 0, then a following direct write to DBGDTRTX, or in AArch64 state to DBGDTR_EL0, writes the intended value, and indirectly writes 1 to DCCSR.TXfull as a side-effect.

No context synchronization operation is required between these two instructions. Overrun and underrun detection prevents intervening external reads and external writes affecting the outcome of the second instruction.

The indirect write to the DCC flags as part of the DTR access instruction is made atomically with the DTR access.

Because a direct read of DBGDTRRX is an indirect write to DCCSR.RXfull, it must occur in program order with respect to the direct read of DCCSR, meaning it must not return a speculative value for DTTRX that predates the RXfull flag returned by the read of DCCSR. The direct write to DBGDTRTX must not be executed speculatively.

Direct reads of DBGDTRRX, or in AArch64 state DBGDTR_EL0, and DCCSR, must occur in program order with respect to other direct reads of the same register using the same encoding.

The following accesses have an implied order within the atomic access:

- In the simple sequential execution of the program the indirect write of the DCC flags occurs immediately after the direct DTR access.

  Note

  For an access to DBGDTR_EL0, this means the indirect write happens after both DBGDTRRX_EL0 and DBGDTRTX_EL0 have been accessed.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- In the simple sequential execution model, for an external read of DBGDTRTX_EL0 or an external write of DBGDTRRX_EL0:
  - The check of the DCC flags for overrun or underrun occurs immediately before the access.
  - If there is no underrun or overrun, the update of the DCC flags occurs immediately after the access.
  - If there is underrun or overrun, the update of the DCC underrun or overrun flags occurs immediately after the access.

All observers must observe the same order for accesses.

Note

These requirements do not create order where order does not otherwise exist. It applies only for ordered accesses.

Without explicit synchronization following external writes and external reads:

- The value written by the external write to DBGDTRRX_EL0 that does not overrun, must be observable to direct reads of DBGDTRRX and DBGDTR_EL0 in finite time.
- The DCC flags that are updated as a side-effect of the external write or external read must be observable:
  - To subsequent external reads of EDSCR.
  - To subsequent external reads of DBGDTRRX_EL0 when checking for underrun.
  - To subsequent external writes to DBGDTRTX_EL0 when checking for overrun.
  - To direct reads of DCCSR in finite time.

However, explicit synchronization is required to guarantee that a direct read of DCCSR returns up-to-date DCC flags. This means that if a signal is received from another agent that indicates that DCCSR must be read, an `ISB` is required to ensure that the direct read of DCCSR occurs after the signal has been received. This also synchronizes the value in DBGDTRRX, if applicable. However, if that signal is an interrupt exception triggered by **COMMIRQ**, **COMMTX**, or **COMMRX**, the exception entry is sufficient synchronization. See *Synchronization of DCC interrupt request signals* on page H4-4772.

Explicit synchronization is required following a direct read or direct write:

- To ensure that a value directly written to DBGDTRTX is observable to external reads of DBGDTRTX_EL0.
- To ensure that a value directly written to DBGDTR_EL0 is observable to external reads of DBGDTRTX_EL0 and DBGDTRRX_EL0.
- To guarantee that the indirect writes to the DCC flags that were a side-effect of the direct read or direct write have occurred, and therefore that the updated values are:
  - Observable to external reads of EDSCR.
  - Observable to external reads of DBGDTRRX_EL0 when checking for underrun.
  - Observable to external writes of DBGDTRTX_EL0 when checking for overrun.
  - Returned by a following direct read of DCCSR.

See also *Memory-mapped accesses to the DCC and ITR* on page H4-4764 and *Synchronization of changes to the external debug registers* on page H8-4812.

Note

These ordering rules mean that software:

- Must not read DBGDTRRX without first checking DCCSR.RXfull or if the previously-read value of DCCSR.RXfull is 0.

  It is not sufficient to read both registers and then later decide whether to discard the read value, as there might be an intervening write from the external debug interface.
- Must not write DBGDTRTX without first checking DCCSR.TXfull or if the previously-read value of DCCSR.TXfull is 1.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

The write to DBGDTRTX overwrites the value in DTRTX, and the external debugger might or might not have read this value.

- Must ensure there is an explicit context synchronization operation following a DTR access, even if not immediately returning to read DCCSR again. This synchronization operation can be an exception return.

Derived requirements

The rules for DCC accesses in Non-debug state are as follows:

- Following a direct read of DBGDTRRX when RXfull is 1:
  - If an external write to DBGDTRRX checks the RXfull flag for overrun and observes that the value of RXfull is 0, the value returned by the previous direct read must not be affected by the external write.
  - If an external read of EDSCR returns a RXfull value of 0, then the value returned by the previous direct read must not be affected by a following external write to DBGDTRRX, and the following external write does not overrun.
- Following a direct read of DBGDTR_EL0, when RXfull is 1:
  - If an external write to DBGDTRRX checks the RXfull flag for overrun and observes that the value of RXfull is 0, the value returned by the previous direct read must not be affected by the external write nor by a following direct write to DBGDTRTX.
  - If an external read of EDSCR returns a RXfull value of 0, then the value returned by the previous direct read must not be affected by subsequent external writes to DBGDTRRX and DBGDTRTX in any order, and the following external write of DBGDTRRX will not overrun.
- Following a direct write to DBGDTRTX, when TXfull is 0:
  - If an external read of DBGDTRTX checks the TXfull flag for underrun and observes that the value of TXfull is 1, the value returned by the external read must be the value written by the previous direct write.
  - If an external read of EDSCR returns a TXfull value of 1, then the value returned by a following external read of DBGDTRRX must be the value written by the previous direct read, and the subsequent external read will not underrun.
- Following a direct write to DBGDTR_EL0, when TXfull is 0:
  - If an external read of DBGDTRTX checks the TXfull flag for underrun and observes that the value of TXfull is 1, the values returned by the external read and by a subsequent external read of DBGDTRRX must be the value written by the previous direct write.
  - If an external read of EDSCR returns a TXfull value of 1, then the value returned by subsequent external reads of DBGDTRRX and DBGDTRTX, in any order, must be the value written by the previous direct read, and the subsequent external read of DBGDTRTX does not underrun.
- Following an external read of DBGDTRTX that does not underrun, if a direct read of DCCSR returns a TXfull value of 0, then the value returned by the external read must not be affected by a following direct write to DBGDTRTX.
- Following a first external read DBGDTRRX and a following second external read of DBGDTRTX that does not underrun, if a direct read of DCCSR returns a TXfull value of 0, then the values returned by the external reads must not be affected by a following direct write to DBGDTR_EL0.
- Following an external write to DBGDTRRX that does not overrun, if a direct read of DCCSR returns an RXfull value of 1, then the value returned by a following direct read of DBGDTRRX or DBGDTR_EL0 must be the value written by the previous external write.
- Following a first external write to DBGDTRTX and a following second external write to DBGDTRRX that does not overrun, if a direct read of DCCSR returns an RXfull value of 1, then the value returned by a subsequent direct read of DBGDTR_EL0 must return the values written by the previous external writes.

H4.5.3 Synchronization of DCC interrupt request signals

Following an external read or external write access to the DTR registers, the interrupt request signals, **COMMIRQ**, **COMMTX**, and **COMMRX**, must be updated in finite time without explicit synchronization.

The updated values must be observable to a direct read of DCCSR or DBGDTRRX, or a direct write of DBGDTRTX executed after taking an interrupt exception generated by the interrupt request. The updated values must also be observable to a direct write of DBGDTRTX executed after taking an interrupt exception generated by the interrupt request.

Following a direct read of DBGDTRRX or a direct write to DBGDTRRX, software must execute a context synchronization operation to guarantee the interrupt request signals have been updated in finite time. This synchronization operation can be an exception return.

H4.5.4 DCC and ITR access in Debug state

In Debug state, stricter observability rules apply for instructions issued through the ITR, to maintain communication between a debugger and the PE, without requiring excessive explicit synchronization.

In Normal access mode, without explicit synchronization:

- A direct read or direct write of the DTR registers by an instruction written to EDITR must be observable to an external write or an external read in finite time:
  - A direct read of DBGDTRRX must be observable to an external write of DBGDTRRX_EL0.
  - A direct read of DBGDTR_EL0 must be observable to an external write of DBGDTRRX_EL0 and DBGDTRTX_EL0.
  - A direct write of DBGDTRTX must be observable to an external read of DBGDTRTX_EL0.
  - A direct write of DBGDTR_EL0 must be observable to an external read of DBGDTRRX_EL0 and DBGDTRTX_EL0.

  This includes the indirect write to the DCC flags that occurs atomically with the access as described in *DCC accesses in Non-debug state* on page H4-4769.

  The subsequent external write or external read must observe either the old or the new values of both the DTR contents and DCC flags. If the old values are observed, this typically results in overrun or underrun, assuming the old values of the DCC flags indicate an overrun or underrun condition, as would normally be the case.

  This means the debugger can observe the direct read or direct write without explicit synchronization and without explicitly testing the DCC flags in EDSCR, because it can rely on overrun and underrun tests.

- External reads of DBGDTRTX_EL0 that do not underrun and external writes to DBGDTRRX_EL0 that do not overrun must be observable to an instruction subsequently written to EDITR on completion of the first external access. This includes the indirect write to the DCC flags.

  This means that without explicit synchronization and without the need to first check the DCC flags in DCCSR:
  - If the instruction is a direct read of DBGDTRRX, it observes the external write.
  - If the instruction is a direct write of DBGDTRTX, it observes the external read.
- Writes to EDITR that do not overrun commit an instruction for execution immediately. The instruction must complete execution in finite time without requiring any further operation by the debugger.
- After an external write to the EDITR, the ITR flags that are updated as a side effect of that write must be observable by:
  - An external read of the EDSCR that follows the external write to the EDITR.
  - When checking for overrun, another external write to the EDITR that follows the original external write to the EDITR.

In Memory access mode, these requirements shift to the instructions implicitly executed by external reads and external writes of the DTR registers, as described in *Memory access mode* on page H4-4762.

H4.6 Interrupt-driven use of the DCC

ARM recommends implementations provide a level-sensitive DCC interrupt request through the IMPLEMENTATION DEFINED interrupt controller as a private peripheral interrupt for the originating PE.

Note

- In addition to connection to the interrupt controller ARM also recommends **COMMIRQ**, **COMMTX**, and **COMMRX** signals that might be implemented for use by any legacy system peripherals.
- GICv3 reserves a private peripheral interrupt number for the **COMMIRQ** interrupt.

The DCCINT register provides a first level of interrupt masking within the PE, meaning only a single interrupt source, **COMMIRQ**, is needed at the interrupt controller.

See also *Synchronization of DCC interrupt request signals* on page H4-4772.

H4.7 Pseudocode description of the operation of the DCC and ITR registers

The basic operation of the DCC and ITR registers is shown by the following pseudocode functions. These functions do not cover the behavior when OSLSR.OSLK == 1, meaning that the OS lock is locked:

- `DBGDTR_EL0[]`.
- `DBGDTRRX_EL0[]`.
- `DBGDTRTX_EL0[]`.
- `EDITR[]`.
- `CheckForDCCInterrupts()`.

For the definition of the DTR Registers, see *shared/debug/dccanditr/DTR* on page J1-5216.

Chapter H5
The Embedded Cross-Trigger Interface

This chapter describes the embedded cross-trigger interface. It contains the following sections:

- *About the Embedded Cross-Trigger (ECT)* on page H5-4776.
- *Basic operation on the ECT* on page H5-4778.
- *Cross-triggers on a PE in an ARMv8 implementation* on page H5-4782.
- *Description and allocation of CTI triggers* on page H5-4783.
- *CTI registers programmers' model* on page H5-4787.
- *Examples* on page H5-4788.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H5.1 About the Embedded Cross-Trigger (ECT)

The *Embedded Cross-Trigger*, ECT, allows a debugger to:

- Send trigger events to a PE. For example, this might be done to halt the PE.
- Send a trigger event to one or more PEs when a trigger event occurs on another PE. For example, this might be done to halt all PEs when one individual PE halts.

Figure H5-1 shows the logical structure of an ECT.

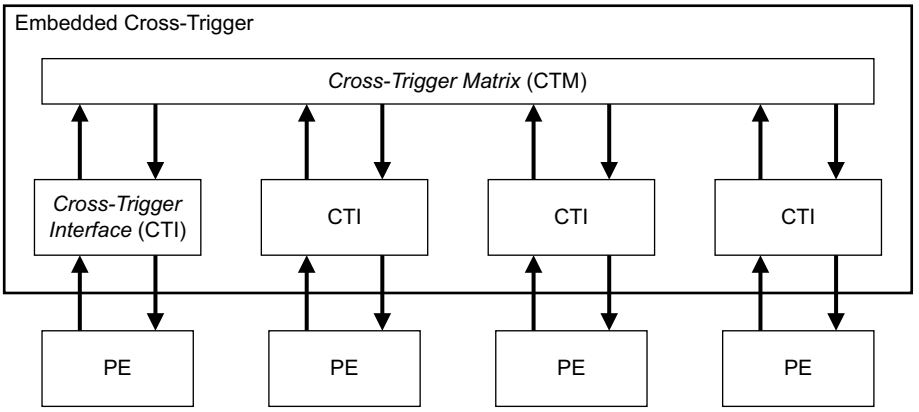

Figure H5-1 Structure of an embedded cross-trigger

The ECT can deliver many types of trigger events, which are described in the following sections:

- *Debug request trigger event* on page H5-4784.
- *Restart request trigger event* on page H5-4784.
- *Cross-halt trigger event* on page H5-4784.
- *Performance Monitors overflow trigger event* on page H5-4785.
- *Generic trace external input trigger events* on page H5-4785.
- *Generic trace external output trigger events* on page H5-4785.
- *Generic CTI interrupt trigger event* on page H5-4785.

An ARMv8-A implementation must:

- Include a cross-trigger interface, CTI.
- Implement at least the input and output triggers defined in this architecture.

See *Cross-triggers on a PE in an ARMv8 implementation* on page H5-4782.

In addition, ARM recommends that the cross-trigger includes:

- The ability to route trigger events between Trace extensions:
  - These typically have advanced event triggering logic.
- An output trigger to the interrupt controller.

Note

The ECT and CTI must only signal trigger events for external debugging. They must not route software events, such as interrupts. For example, the Performance Monitors overflow input trigger is provided to allow entry to Debug state on a counter overflow, and the output trigger to the interrupt controller is provided to generally allow events from the external debug sub-system to be routed to a software agent. However, the combination of the two must not be used as a mechanism to route Performance Monitors overflows to an interrupt controller.

H5.2 Basic operation on the ECT

The ECT comprises a Cross-Trigger Matrix, CTM, and one Cross-Trigger Interface, CTI, for each PE. The CTM passes events between the CTI blocks over channels. The CTM can have a maximum of 32 channels.

The main interfaces of the cross-trigger interface, CTI, are:

- The input triggers:
  - These are trigger event inputs from the PE to the CTI.
- The output triggers:
  - These are trigger event outputs from the CTI to the PE.
- The input channels:
  - These are channel event inputs from the cross-trigger matrix, CTM, to the CTI.
- The output channels:
  - These are channel event outputs from the CTI to the CTM.

Each CTI block has:

- Up to 32 input triggers that come from the PE:
  - The input triggers are numbered 0-31.
- Up to 32 output triggers that go to the PE:
  - The output triggers are numbered 0-31.

Figure H5-2 on page H5-4779 shows the logical internal structure of a CTI.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

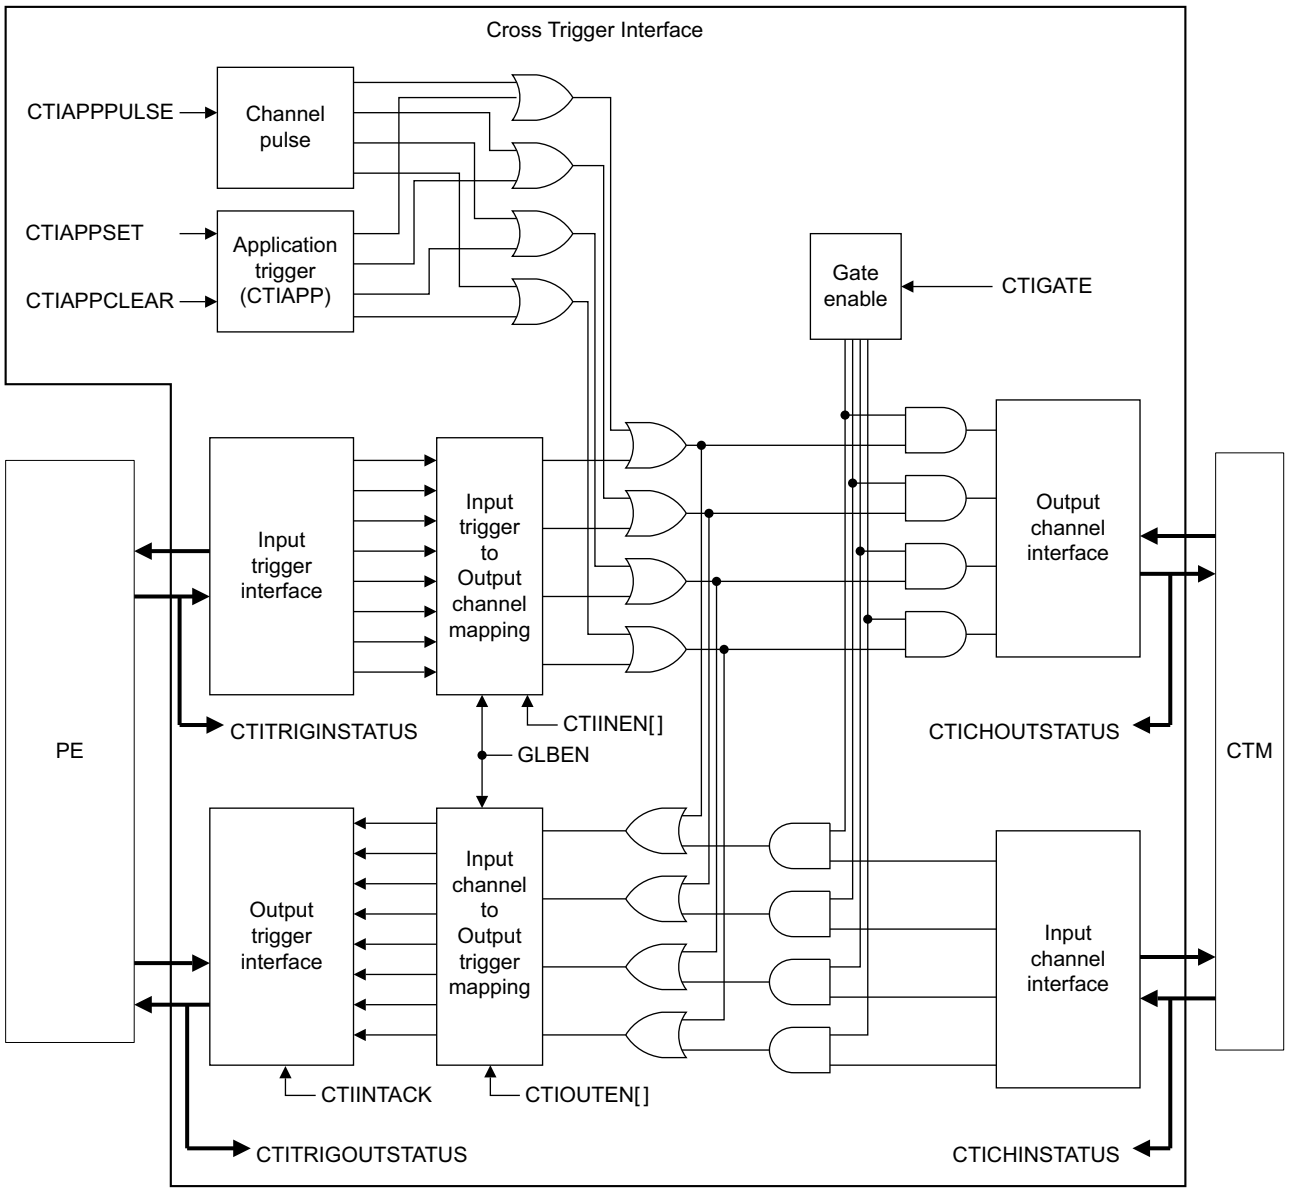

Figure H5-2 Structure of a cross-trigger interface

Note

- The number of triggers in IMPLEMENTATION DEFINED. Figure H5-2 shows eight input and eight output triggers.
- The number of channels is IMPLEMENTATION DEFINED. Figure H5-2 shows four channels.
- In Figure H5-2 the input channel gate function is a CTIv2 feature.

When the CTI receives an input trigger event, this generates channel events on one or more internal channels, according to the *mapping function* defined by the *Input trigger→output channel mapping registers*, CTIINEN<n>.

The CTI also contains an *application trigger* and *channel pulse* to allow a debugger to create channel events directly on internal channels by writing to the CTI control registers.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Channel events on each internal channel are passed to a corresponding output channel that is controlled by a *channel gate*. The channel gate can block propagation of channel events from an internal channel to an output channel.

The output channels from a CTI are combined, using a logical OR function, with the output channels from all other CTIs to form the input channels on other CTIs. The input channels of this CTI are the logical OR of the output channels on all other CTIs. This is the *cross-trigger matrix*, CTM. Therefore, the number of input channels must equal the number of output channels.

Note

The number of input triggers and output triggers is not required to be the same.

The internal channels form an internal cross-trigger matrix within the CTI. This delivers events directly from the input triggers to the output triggers. Therefore the number of internal channels is the same as the number of input and output channels on the external CTM, and there is a direct mapping between the two.

Channel events received on each input channel are passed to the corresponding internal channel. It is IMPLEMENTATION DEFINED whether the cross-trigger gate also blocks propagation of channel events from input channels to internal channels.

When the CTI receives a channel event on an internal channel this generates trigger events on one or more output triggers, according to the mapping function defined by the *Input channel → output trigger mapping registers*, CTIOUTEN<n>.

The CTI contains the input and output trigger interfaces to the PE and the interface of the cross-trigger matrix. The architecture does not define the signal protocol used on the trigger interfaces, and:

- It is IMPLEMENTATION DEFINED whether the CTI supports multicycle input trigger events.
- It is IMPLEMENTATION DEFINED whether the CTM supports multicycle channel events.

See *Multicycle events*.

However, an output trigger is asserted until acknowledged. The output trigger can be:

- Self-acknowledging. This means that no further action is required from the debugger.
- Acknowledged by the debugger writing 1 to the corresponding bit of CTIINTACK.

The time taken to propagate a trigger event from the first PE, through its CTI, across the CTM to another CTI, and thereby to a second PE is IMPLEMENTATION DEFINED.

Note

ARM recommends that this path is not longer than the shortest software communication path between those PEs. This is because if the first PE halts, the Cross-halt trigger event can propagate through the ECT and halt the second PE without causing software on the second PE to malfunction because the first PE is in Debug state and is not responding.

H5.2.1 Multicycle events

A multicycle event is one with a continuous state that might persist over many cycles, as opposed to a discrete event. A typical implementation of a multicycle event is a level-based signal interface, whereas a discrete event might be implemented as a pulse signal or message.

CTI support for multicycle trigger events is IMPLEMENTATION DEFINED. Use of multicycle trigger events is deprecated. Of the architecturally defined input trigger events, the Performance Monitors overflow trigger event and Generic trace external output trigger events can be multicycle input triggers.

CTM support for multicycle channel events is IMPLEMENTATION DEFINED. A CTM that does not support multicycle channel events cannot propagate a multicycle trigger event between CTIs.

Note

A full ECT might comprise a mix of CTIs, some of which can support multicycle trigger events. In bridging these components, multicycle channel events become single channel events at the boundary between the CTIs.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

An ECT that supports multicycle trigger events

When an ECT supports multicycle trigger events, an input trigger event to the CTI continuously asserts channel events on all output channels mapped to it until either:

- The input trigger event is removed.
- The channel mapping function is disabled.

This means that an input trigger that is asserted for multiple cycles causes any channels that are mapped to it to become active for multiple cycles. Consequently, any output triggers mapped from that channel are asserted for multiple cycles.

Note

The output trigger remains asserted for at least as long as the channel remains active. This means that even if the output trigger is acknowledged, it remains asserted until the channel deactivates.

The CTI does not guarantee that these events have precisely the same duration, as the triggers and channels can cross between clock domains.

CTIAPPSET and CTIAPPCLEAR can set a channel active for multiple cycles. CTIAPPPULSE generates a single channel event. CTICHINSTATUS and CTICHOUTSTATUS can report whether a channel is active.

An ECT that does not support multicycle trigger events

When an ECT does not support multicycle trigger events, an input trigger event to the CTI generates a single channel event on all output channels mapped to it, regardless of how long the input trigger event is asserted.

This means that an input trigger event that is asserted for multiple cycles generates a single channel event on any channels mapped to it. Consequently any self-acknowledging output triggers mapped from those channels are single trigger events.

Note

A single event is typically a single cycle, but there is no guarantee that this is always the case.

CTIAPPSET and CTIAPPCLEAR can only generate a single channel event. CTIAPPPULSE generates a single channel event. If the ECT does not support multicycle channel events, use of CTIAPPSET and CTIAPPCLEAR is deprecated, and the debugger must only use CTIAPPPULSE. CTICHINSTATUS and CTICHOUTSTATUS must be treated as UNKNOWN.

Non-Confidential - Beta

H5.3 Cross-triggers on a PE in an ARMv8 implementation

An ARMv8 PE must include a cross-trigger interface, and the implementation must include at least the input and output triggers defined in this architecture. The number of channels in the cross-trigger matrix is IMPLEMENTATION DEFINED, but there must be a minimum of three. Software can read CTIDEVID.NUMCHAN to discover the number of implemented channels.

The CTM must connect to all PEs in the same Inner Shareability domain as the ARMv8-A PE, but can also connect to additional PEs. ARM strongly recommends that the CTM connects all PEs implementing a CTI in the system. This includes ARMv7-A PEs and other PEs that can be connected using a CoreSight CTI module.

Note

In a uniprocessor system the CTM is OPTIONAL. The CTM might be connected other CTI modules for non-PEs, such as triggers for system visibility components. ARM recommends that the CTM is implemented.

Any CTI connected to a PE that is not an ARMv8-A PE must implement at least:

- The Debug request trigger event.
- The Restart trigger event.
- The Cross-halt trigger event.

For more information about the CTI, see the *CoreSight ™ SoC Technical Reference Manual*. ARMv8-A refines the generic CTI by defining roles for each of the implemented input and output triggers.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H5.4 Description and allocation of CTI triggers

Table H5-1 shows the output trigger events defined by the architecture and the related trigger numbers.

Table H5-1 Allocation of CTI output trigger events

Number	Source	Destination	Event description
0	CTI	PE	*Debug request trigger event* on page H5-4784
1	CTI	PE	*Restart request trigger event* on page H5-4784
2	CTI	IRQ controller	*Generic CTI interrupt trigger event* on page H5-4785
3	-	-	Reserved
4 - 7	CTI	Trace extension	OPTIONAL *Generic trace external input trigger events* on page H5-4785

Note

Output triggers from the CTI are inputs to other blocks.

Table H5-2 shows the input trigger events defined by the architecture and the related trigger numbers.

Table H5-2 Allocation of CTI input trigger events

Number	Source	Destination	Event description
0	PE	CTI	*Cross-halt trigger event* on page H5-4784
1	PE	CTI	*Performance Monitors overflow trigger event* on page H5-4785
2 - 3	-	-	Reserved
4 - 7	Trace extension	CTI	OPTIONAL *Generic trace external output trigger events* on page H5-4785

Note

Input triggers to the CTI are outputs from other blocks.

Table H5-1 and Table H5-2 show the minimum set of trigger events defined by the architecture. However:

- The Generic trace external input and output trigger events are only required if the OPTIONAL Trace extension is implemented. If the OPTIONAL Trace extension is not implemented, these trigger events are reserved.
- Support for the generic CTI interrupt trigger event is IMPLEMENTATION DEFINED because details of interrupt handling in the system, including any interrupt controllers, are IMPLEMENTATION DEFINED. Details regarding how the CTI interrupt is connected to an interrupt controller and its allocated interrupt number lie outside the scope of the architecture. ARM strongly recommends that implementations provide a means to generate interrupts based on external debug events.
- The other trigger events are required by the architecture.

An ARMv8-A implementation can extend the CTI with additional triggers. These start with the number eight.

Non-Confidential - Beta

H5.4.1 Debug request trigger event

This is an output trigger event from the CTI, and an input trigger event to the PE, asserted by the CTI to force the PE into Debug state. The trigger event is asserted until acknowledged by the debugger. The debugger acknowledges the trigger event by writing 1 to CTIINTACK[0].

Note

A debugger must poll CTITRIGOUTSTATUS[0] until it reads as 0, to confirm that the output trigger has been deasserted before generating any event that must be ordered after the write to CTIINTACK.

If the PE is already in Debug state, the PE ignores the trigger event, but the CTI continues to assert it until it is removed by the debugger. See also *External Debug Request debug event* on page H3-4750.

H5.4.2 Restart request trigger event

This is an output trigger event from the CTI, and an input trigger event to the PE, asserted by the CTI to request the PE to exit Debug state. If the PE is in Non-debug state, the request is ignored and dropped by the CTI.

If a Restart request trigger event is received at or about the same time as the PE enters Debug state, it is CONSTRAINED UNPREDICTABLE whether:

- The restart is ignored. In this case the PE enters Debug state and remains in Debug state.
- The PE enters Debug state and then immediately restarts.

Debuggers must program the CTI to send Restart request trigger events only to PEs that are halted. To enable the PE to disambiguate discrete Restart request trigger events, after sending a Restart request trigger event, the debugger must confirm that the PE has restarted and halted before sending another Restart request trigger event. Debuggers can use EDPRSR.{SDR, HALTED} to determine the Execution state of the PE.

Note

Before generating a Restart request trigger event for a PE, a debugger must ensure any Debug request trigger event targeting that PE is cleared. *Debug request trigger event* describes how to do this.

The trigger event is self-acknowledging, meaning that the debugger requires no further action to remove the trigger event. See also *Exiting Debug state* on page H2-4730.

H5.4.3 Cross-halt trigger event

This is an input trigger event to the CTI, and an output trigger event from the PE, asserted by a PE when it is entering Debug state.

Note

To reduce the latency of halting, ARM recommends that an implementation issues the Cross-halt trigger event early in the committed process of entering Debug state. This means that there is no requirement to wait until all aspects of entry to Debug state have completed before issuing the trigger event. Speculative emission of Cross-halt trigger events is not allowed. The Cross-halt trigger event must not be issued early enough for a subsequent Debug request trigger event, that might be derived from the Cross-halt trigger event, to be recorded in the EDSCR.STATUS field. This applies to Debug request trigger events that are acting as inputs to the PE.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H5.4.4 Performance Monitors overflow trigger event

This is an input trigger event to the CTI, and an output trigger event from the PE, asserted each time the PE asserts a new Performance Monitors counter overflow interrupt request. See Chapter D5 *The Performance Monitors Extension*.

If the CTI supports multicycle trigger events, then the trigger event remains asserted until the overflow is cleared by a write to PMOVSCLR_EL0. Otherwise, the trigger event is asserted when the value of PMOVSCLR_EL0 changes from zero to a non-zero value.

Note

- This does not replace the recommended connection of Performance Monitors overflow trigger event to an interrupt controller. Software must be able to program an interrupt on Performance Monitors overflow without programming the CTI.
- Events can be counted when `ExternalNoninvasiveDebugEnabled()` == FALSE, and, in Secure state, when `ExternalSecureNoninvasiveDebugEnabled()` == FALSE. Secure software must be aware that overflow trigger events are nevertheless visible to the CTI.

H5.4.5 Generic trace external input trigger events

These are output trigger events from the CTI, and input trigger events to the OPTIONAL Trace extension, that are used in conjunction with the Generic trace external output trigger events to pass trigger events between:

- The PE and the OPTIONAL Trace extension.
- The OPTIONAL Trace extension and any other component attached to the CTM, including other Trace extensions.

There are four Generic trace external input trigger events.

The trigger events are self-acknowledging. This means that the debugger does not have to take any further action to to remove the events.

H5.4.6 Generic trace external output trigger events

These are input trigger events to the CTI, and output trigger events from the OPTIONAL Trace extension, used in conjunction with the Generic trace external input trigger events to pass trigger events between:

- The PE and the OPTIONAL Trace extension.
- The OPTIONAL Trace extension and any other component attached to the CTM, including other Trace extensions.

There are four Generic trace external output trigger events.

H5.4.7 Generic CTI interrupt trigger event

This is an output trigger event from the CTI, and an input to an IMPLEMENTATION DEFINED interrupt controller, and can transfer trigger events from the PE, Trace extension, or any other component attached to the CTI and CTM to software as an interrupt. The Generic CTI interrupt trigger event must be connected to the interrupt controller as an interrupt that can target the originating PE.

Note

- ARM recommends that the Generic CTI interrupt trigger event is a private peripheral interrupt, but implementations might instead make this trigger event available as a shared peripheral interrupt or a local peripheral interrupt.
- GICv3 reserves a private peripheral interrupt number for this interrupt.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

It is IMPLEMENTATION DEFINED whether this trigger event is:

- Self-acknowledging. This means that the debugger is not required to take any further action, and that the interrupt controller must treat the trigger event as a pulse or edge-sensitive interrupt.
- Acknowledged by the debugger. The debugger acknowledges the trigger event by writing 1 to CTIINTACK[2]. This means that the interrupt controller must treat the trigger event as a level-sensitive interrupt.

ARM recommends that the Generic CTI interrupt trigger event is a self-acknowledging trigger event.

H5.5 CTI registers programmers' model

The CTI registers programmers' model is described in Chapter H8 *About the External Debug Registers*. The following sections contain information specific to the CTI:

- *External debug register resets* on page H8-4829.
- *External debug interface register access permissions* on page H8-4818.
- *Cross-trigger interface registers* on page H8-4827.
- The individual register descriptions in *Cross-Trigger Interface registers* on page H9-4919.

See also *Memory-mapped accesses to the external debug interface* on page H8-4816.

H5.5.1 CTI reset

An External Debug reset resets the CTI. See *External debug register resets* on page H8-4829 for details of CTI register resets. All CTI output triggers and output channels are deasserted on an External Debug reset.

H5.5.2 CTI authentication

The CTI ignores the state of the IMPLEMENTATION DEFINED authentication interface. This means that:

- CTITRIGINSTATUS shows the status of the input triggers and CTICHINSTATUS shows the status of the input channels, regardless of the value of `ExternalNoninvasiveDebugEnabled()`.

  Note

  The PE does not generate the Cross-halt trigger event and the Trace extension does not generate Generic trace external output trigger events when `ExternalNoninvasiveDebugEnabled()` == FALSE. However, the PE can generate Performance Monitors overflow trigger events.

- The CTI can generate external triggers regardless of the value of `ExternalInvasiveDebugEnabled()`.

  Note

  The PE ignores Debug request and Restart request trigger events when `ExternalInvasiveDebugEnabled()` == FALSE. The Trace extension ignores Generic trace external input trigger events when `ExternalNoninvasiveDebugEnabled()` == FALSE. The behavior of Generic CTI interrupt requests is part of the IMPLEMENTATION DEFINED handling of these interrupts, but it is permissible for an interrupt controller to receive these requests even when `ExternalInvasiveDebugEnabled()` == FALSE.

Non-Confidential - Beta

H5.6 Examples

The CTI is fully programmable and allows for flexible cross-triggering of events within a PE and between PEs in a multiprocessor system. For example:

- The Cross-halt trigger event and the Debug request trigger event can be used for cross-triggering in a multiprocessor system.
- The Cross-halt trigger event and the Generic interrupt trigger event can be used for event-driven debugging in a multiprocessor system.
- The Performance Monitors overflow trigger event and the Debug request trigger event can force entry to Debug state on overflow of a Performance Monitors event counter, for event-driven profiling.

  Note

  This does not replace the recommended connection of Performance Monitors overflow trigger events to an interrupt controller. Software must be able to program an interrupt on Performance Monitors overflow without programming the CTI. ARM recommends that the Performance Monitors overflow signal is directly available as a local interrupt source.

- The Generic trace external input and Generic trace external output trigger events can pass trace events into and out of the event logic of the Trace extension. They can do this:
  - To pass trace events between Trace extensions.
  - In conjunction with the Performance Monitors overflow trigger event, to couple the Performance Monitors to the Trace extension.
  - In conjunction with the Debug request trigger event, to trigger entry to Debug state on a trace event.
  - In conjunction with other CTIs, to signal a trace trigger event onto a CoreSight trace interconnect.

The following sections describe some examples in more detail:

- *Halting a single PE*.
- *Halting all PEs in a group when any one PE halts* on page H5-4789.
- *Synchronously restarting a group of PEs* on page H5-4789.
- *Halting a single PE on Performance Monitors overflow* on page H5-4790.

Example H5-1 Halting a single PE

To halt a single PE, set:

1. CTIGATE[0] to 0, so that the CTI does not pass channel events on internal channel 0 to the CTM.
2. CTIOUTEN0[0] to 1, so that the CTI generates a Debug request trigger event in response to a channel event on channel 0.

   Note

   The Cross-halt trigger event is input trigger 0, meaning it is controlled by the instance of CTIOUTEN<n> for which <n> is 0.

3. CTIAPPPULSE[0] to 1, to generate a channel event on channel 0.

When the PE has entered Debug state, clear the Debug request trigger event by writing 1 to CTIINTACK[0], before restarting the PE.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Example H5-2 Halting all PEs in a group when any one PE halts

To program a group of PEs so that when one PE in the group halts, all of the PEs in that group halt, set the following registers for each PE in the group:

1. CTIGATE[2] to 1, so that each CTI passes channel events on internal channel 2 to the CTM.
2. CTIINEN0[2] to 1,so that each CTI generates a channel event on channel 2 in response to a Cross-halt trigger event.
3. CTIOUTEN0[2] to 1, so that each CTI generates a Debug request trigger event in response to an channel event on channel 2.

   Note

   The Cross-halt trigger event is input trigger 0, meaning it is controlled by the instances of CTIINEN<n> and CTIOUTEN<n> for which <n> is 0.

When a PE has halted, clear the Debug request trigger event by writing a value of 1to CTIINTACK[0], before restarting the PE.

Example H5-3 Synchronously restarting a group of PEs

To restart a group of PEs, for each PE in the group:

1. If the PE was halted because of a Debug request trigger event, the debugger must ensure the trigger event is deasserted. It can do this by:
   a. Writing 1 to CTIINTACK[0] to clear the Debug request trigger event.
   b. Polling CTITRIGOUTSTATUS[0], until it reads as 0, to confirm that the trigger event has been deasserted.
2. Set CTIGATE[1] to 1, so that each CTI passes channel events on internal channel 1 to the CTM.
3. Set CTIOUTEN1[1] to 1, so that each CTI generates a Restart request trigger event in response to a channel event on channel 1.

   Note

   This example must use the instance of CTIOUTEN<n> for which <n> is 1.

4. Set CTIAPPPULSE[1] to 1 on any one PE in the group, to generate a channel event on channel 1.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Example H5-4 Halting a single PE on Performance Monitors overflow

To halt a single PE on a Performance Monitors overflow set:

1. CTIGATE[3] to 0, so that the CTI does not pass channel events on internal channel 3 to the CTM.
2. CTIINEN1[3] to 1, so that the CTI generates a channel event on channel 3 in response to a Performance Monitors overflow trigger event.

   Note

   This step of this example must use the instance of CTIINEN<n> for which <n> is 1.

3. CTIOUTEN0[3] to 1, so that the CTI generates a Debug request trigger event in response to a channel event on channel 3.

   Note

   This step of this example must use the instance of CTIOUTEN<n> for which <n> is 0.

When the PE has entered Debug state, clear the Debug request trigger event by writing 1 to CTIINTACK[0], before restarting the PE. Clear the overflow status by writing to PMOVSCLR_EL0.

Chapter H6
Debug Reset and Powerdown Support

This chapter describes the reset and powerdown support in the Debug architecture. It contains the following sections:

- *About Debug over powerdown* on page H6-4792.
- *Power domains and debug* on page H6-4793.
- *Core power domain power states* on page H6-4794.
- *Emulating low-power states* on page H6-4796.
- *Debug OS Save and Restore sequences* on page H6-4798.
- *Reset and debug* on page H6-4802.

Note

Where necessary, Table K13-1 on page K13-5568 disambiguates the general register references used in this chapter.

Non-Confidential - Beta

H6.1 About Debug over powerdown

Debug over powerdown is a facility for an operating system to save and restore the PE state on behalf of a self-hosted or external debugger or both.

For external debug over powerdown, the architecture defines the OS Lock, OS Double Lock, and the logical split of the hardware on which a PE executes into the *Core power domain* and the *Debug power domain*. See:

- *Power domains and debug* on page H6-4793.
- *Core power domain power states* on page H6-4794.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H6.2 Power domains and debug

The external debug component of ARMv8-A has two logical power domains, each with its own reset:

- The debug power domain contains the interface between the PE and the external debugger, and is powered up whenever an external debugger is connected to the SoC. It remains powered up while the external debugger is connected. Registers in this domain are reset by an external debug reset.
- The core power domain contains the rest of the PE, and is allowed to power up and power down independently of the Debug power domain.

The core power domain contains several types of registers:

- Non-debug logic refers to all registers and logic that are not associated with debug.
- Self-hosted debug logic refers to registers and logic associated solely with the self-hosted debug aspects of the architecture.
- Shared debug logic refers to registers and logic associated with both the self-hosted and external debug aspects of the architecture.
- External debug logic refers to registers and logic associated solely with the external debug aspects of the architecture.

Note

- The model of two logical power domains has an impact on the reset and access permission requirements of the debug programmers' model.
- The power domains are described as logical because the architecture defines the requirements but does not require two physical power domains. Any power domain split that meets the requirements of the programmers' model is a valid implementation.

Figure H6-1 shows the recommended power domain split. The signals **DBGPWRUPREQ**, **DBGNOPWRDWN**, and **DBGPWRDUP** shown in Figure H6-1 provide an interface between the power controller and the PE debug logic that is in the debug power domain. They are part of the recommended interface. See Appendix K2 *Recommended External Debug Interface*.

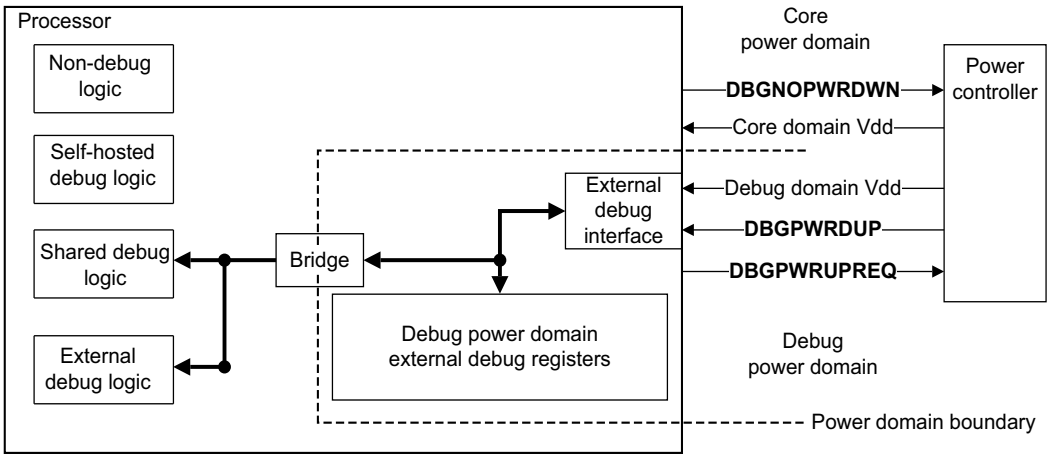

Figure H6-1 Recommended power domain split between core and debug power domains

Non-Confidential - Beta

H6.3 Core power domain power states

The ARM architecture does not define the power states of the PE as these are not normally visible to software. However, they are visible to the external debugger. The Debug architecture uses a four logical power states model for the core power domain. The four logical power states are as follows:

Normal The core power domain is fully powered up and the debug registers are accessible.

Standby The core power domain is on, but there are measures to reduce energy consumption. In a typical implementation, the PE enters standby by executing a `WFI` or `WFE` instruction, and exits on a wake-up event. There can be other IMPLEMENTATION DEFINED measures the OS can take to enter standby.

The PE preserves the PE state, including the debug logic state. Changing from standby to normal operation does not involve a reset of the PE.

Standby is the least invasive OS energy saving state. Standby implies only that the PE is unavailable and does not clear any debug settings. For standby, the Debug architecture requires only the following:

- An External Debug Request debug event is a wake-up event when halting is allowed. This means that the PE must exit standby to handle the debug event. If the PE executed a `WFE` or a `WFI` instruction to enter standby, then it retires that instruction,
- If the external debug interface is accessed, the PE must respond to that access. ARM recommends that, if the PE executed a `WFI` or `WFE` instruction to enter standby, then it does not retire that instruction.

Standby is transparent, meaning that to software and to an external debugger it is indistinguishable from normal operation.

Retention The OS takes some measures, including IMPLEMENTATION DEFINED code sequences and registers, to reduce energy consumption. The PE state, including debug settings, is preserved in low-power structures, allowing the core power domain to be at least partially turned off.

Changing from low-power retention to normal operation does not involve a reset of the PE. The saved PE state is restored on changing from low-power retention state to normal operation. If software has to use an IMPLEMENTATION DEFINED code sequence before entering, or after leaving, a retention state, this is referred to as a *software-visible retention state*. It is IMPLEMENTATION DEFINED whether the value of DBGPRCR.CORENPDRQ is set to the value of EDPRCR.COREPURQ on leaving the software-visible retention state.

External Debug Request debug events stay pending and debug registers in the core power domain cannot be accessed.

Note

- This model of retention does not include implementations where the PE exits the state in response to a debug register access. From the Debug architecture perspective, implementations like this are forms of standby.

Powerdown The OS takes some measures to reduce energy consumption by turning the core power domain off. These measures must include the OS saving any PE state, including the debug settings, that must be preserved over powerdown. Changing from powerdown to normal operation must include:

- A Cold reset of the PE after the power level has been restored.
- The OS restoring the saved PE state.

External Debug Request debug events stay pending and debug registers in the core power domain cannot be accessed.

An implementation might support enabling and disabling threads, either dynamically or once at reset time. Threads that are disabled in this way must appear to the external debugger as either:

- Powered off , meaning they are either:
  - In a powerdown state.
  - In a retention state.
- Held in Reset state.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

The Debug architecture uses a simpler two states model for the Debug power domain. The two states are:

Off The debug power domain is turned off.

On The debug power domain is turned on.

The available power states, including the cross-product of core power domain and debug power domain power states is IMPLEMENTATION DEFINED. Implementations are not required to implement all of these states and might include additional states. These additional states must appear to the debugger as one of the logical power states defined by this model. The control of power states is IMPLEMENTATION DEFINED.

Note

As a result, it is IMPLEMENTATION DEFINED whether it is possible for the debug power domain to be on when the core power domain is off.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H6.4 Emulating low-power states

The control registers DBGPRCR.CORENPDRQ and EDPRCR.COREPURQ provide an interface between the power controller and the PE. They typically map directly to signals in the recommended external debug interface. With this interface the external debugger can request the power controller to:

- Emulate states where the core power domain is completely off or in a low-power state where the core power domain registers cannot be accessed. This simplifies the requirements on software by sacrificing entirely realistic behavior.
- Restore full power to the core power domain.

EDPRSR.{SPD, PU} indicates the core power domain power state. For more information see:

- *DBGPRCR_EL1, Debug Power Control Register* on page D7-2082 and *DBGPRCR, Debug Power Control Register* on page G6-4578.
- *EDPRCR, External Debug Power/Reset Control Register* on page H9-4896.
- *EDPRSR, External Debug Processor Status Register* on page H9-4899.
- Appendix K2 *Recommended External Debug Interface*.

The measures to emulate powerdown are IMPLEMENTATION DEFINED. The ability of the debugger to access the state of the PE and the system might be limited as a result of the measures adopted.

In an emulated powerdown state, the debugger must be able to access all debug registers in both the debug power domain and the core power domain as if the core power domain were on. That is, the debugger must be able to read and write to such registers without receiving errors. This allows an external debugger to debug the powerup sequence. To stop the OS Double Lock preventing access to debug registers when powerdown is being emulated, `DoubleLockStatus() == FALSE` when DBGPRCR.CORENPDRQ == 1.

Otherwise, the behavior of the PE in emulated powerdown must be similar to that in a real powerdown state. In particular, the PE must not respond to other system stimuli, such as interrupts.

Example H6-1 and Example H6-2 are examples of two approaches to emulating powerdown.

Example H6-1 An example of emulating powerdown

The PE is held in Standby state, isolated from any system stimuli. It is IMPLEMENTATION DEFINED whether the PE can respond to debug stimuli such as an External Debug Request debug event.

If the PE can enter Debug state, then the external debugger is able to use the ITR to execute instructions, such as loads and stores. This causes the external debugger to interact with the system. If the external debugger restarts the PE, the PE leaves Standby state and restarts fetching instructions from memory.

Example H6-2 Another example of emulating powerdown

The PE is held in Warm reset. This limits the ability of an external debugger to access the resources of the PE. For example, the PE cannot be put into Debug state.

On exit from emulated powerdown the PE is reset. However, the debug registers that are only reset by a Cold reset must not be reset. Typically this means that a Warm reset is substituted for the Cold reset.

Note

- Warm reset and Cold reset have different effects apart from resetting the debug registers. In particular, RMR_ELx is reset by a Cold reset and controls the reset state on a Warm reset. This means that if a Cold reset is substituted by a Warm reset, the behavior of the reset code might be different.
- The timing effects of powering down are typically not factored in the powerdown emulation. Examples of these timing effects are clock and voltage stabilization.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- Emulation does not model the state lost during powerdown, meaning that it might mask errors in the state storage and recovery routines.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H6.5 Debug OS Save and Restore sequences

In ARMv8-A, the following registers provide the OS Save and restore mechanism:

- The *OS Lock Access Register*, OSLAR, locks the OS Lock to restrict access to debug registers before starting an OS Save sequence, and unlocks the OS Lock after an OS Restore sequence.
- The *OS Lock Status Register*, OSLSR, shows the status of the OS Lock.
- The *External Debug Execution Control Register*, EDECR, can be configured to generate a debug event when the OS Lock is unlocked.
- The *OS Double Lock Register*, OSDLR, locks out an external debug interface entirely. This is only used immediately before a powerdown sequence.

See also:

- *Reset and debug* on page H6-4802
- Appendix K8 *Example OS Save and Restore Sequences*

H6.5.1 Debug registers to save over powerdown

Table H6-1 shows the different requirements for self-hosted debug over powerdown and external debug over powerdown:

- The column labeled Self-hosted lists registers that software must preserve over powerdown so that it can support self-hosted debug over powerdown. This does not require use of the OS Save and Restore mechanism.
- The column labeled External lists registers that software must preserve over powerdown so that it can support external debug over powerdown. This requires use of the OS Save and Restore mechanism:
  - Some external debug registers are not normally accessible to software executing on the PE. Additional debug registers are provided that give software the required access to save and restore these external debug registers when OSLSR.OSLK is locked. These registers include OSECCR, OSDTRRX, and OSDTRTX.
- Some registers might only present in some implementations, or might not be accessible at all Exception levels or in Non-secure state. DBGVCR32_EL2 and SDER32_EL3 are only required to support AArch32.

Table H6-1 does not include registers for the OPTIONAL Trace and Performance Monitor extensions.

Table H6-1 Debug registers to save over powerdown

Register in AArch64	Register in AArch32	Self-hosted	External
MDSCR_EL1	DBGDSCRext	Yes	Yes[a]
DBGBVR<n>_EL1	DBGBVR<n>	Yes	Yes
DBGBCR<n>_EL1	DBGBCR<n>	Yes	Yes
DBGWVR<n>_EL1	DBGWVR<n>	Yes	Yes
DBGWCR<n>_EL1	DBGWCR<n>	Yes	Yes
DBGVCR32_EL2	DBGVCR	Yes	-
MDCR_EL2	HDCR	Yes	-
SDER32_EL3	SDER	Yes	-
MDCR_EL3	SDCR	Yes[b]	-

Table H6-1 Debug registers to save over powerdown (continued)

Register in AArch64	Register in AArch32	Self-hosted	External
DBGCLAIMSET_EL1 DBGCLAIMCLR_EL1	DBGCLAIMSET, DBGCLAIMCLR	-	Yes[c]
OSECCR_EL1	DBGOSECCR	-	Yes[ab]
OSDTRRX_EL1 OSDTRTX_EL1	DBGDTRRXext DBGDTRTXext	-	Yes

a. The OS Lock must be locked to save and restore for external debug. When the OS Lock is locked, DSCR is part of the software save and restore mechanism for external debug. It provides a mechanism for an operating system to access some fields of EDSCR that are otherwise read-only or not visible to software. This allows the operating system to save and restore these settings over a powerdown for the external debugger.

b. This register is new in ARMv8-A. Sequences written for ARMv7 do not preserve the register over powerdown.

c. Read DBGCLAIMCLR to save, write DBGCLAIMSET to restore.

H6.5.2 OS Save sequence

To preserve the debug logic state over a powerdown, the state must be saved to nonvolatile storage. This means the OS Save sequence must:

1. Lock the OS Lock by:
   - Writing the key value `0xC5ACCE55` to the DBGOSLAR in AArch32 state.
   - Writing 1 to OSLAR_EL1.OSLK in AArch64 state.
2. Execute an `ISB` instruction.
3. Walk through the debug registers listed in *Debug registers to save over powerdown* on page H6-4798 and save the values to the nonvolatile storage.

Before removing power from the core power domain, software must:

1. Lock the OS Double Lock by writing 1 to OSDLR_EL1.DLK.
2. Execute a context synchronization operation.

H6.5.3 OS Restore sequence

After a powerdown, the OS Restore sequence must perform the following steps to restore the debug logic state from the non-volatile storage:

1. Lock the OS Lock, as described in *OS Save sequence*. The OS Lock is generally locked by the Cold reset, but this step ensures that it is locked.
2. Execute an `ISB` instruction.
3. To ensure that, if an external debugger clears the OS Lock before the end of this sequence, no debug exceptions are generated:
   - Write 0 to MDSCR_EL1 if executing in AArch64 state.
   - Write 0 to DBGDSCRext if executing in AArch32 state.
4. Walk through the debug registers listed in *Debug registers to save over powerdown* on page H6-4798, and restore the values from the nonvolatile storage. The last register to be restored must be:
   - MDSCR_EL1 if executing in AArch64 state.
   - DBGDSCRext if executing in AArch32 state.
5. Execute an `ISB` instruction.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

6. Unlock the OS Lock by:
   - Writing any non-key value to DBGOSLAR if executing in AArch32 state.
   - Writing 0 to OSLAR_EL1.OSLK if executing in AArch64 state.
7. Execute a context synchronization operation.

Note

The OS Restore sequence overwrites the debug registers with the values that were saved. If there are valid values in these registers immediately before the restore sequence, then those values are lost.

H6.5.4 Debug behavior when the OS Lock is locked

The main purpose of the OS Lock is to prevent updates to debug registers during an OS Save or OS Restore operation. The OS Lock is locked on a Cold reset.

When the OS Lock is locked:

- Access to debug registers through the System register interface is mainly unchanged except that:
  - Certain registers are read and written without side-effects.
  - Fields in DSCR and OSECCR that are normally read-only become read/write.

  This allows the state to be saved or restored. For more information, see the relevant register description in Chapter H9 *External Debug Register Descriptions*.
- Access to debug registers by the external debug interface is restricted to prevent an external debugger modifying the registers that are being saved or restored. For more information see *External debug interface register access permissions summary* on page H8-4819.
- Debug exceptions, other than Software Breakpoint Instruction exceptions are not generated.

The OS Lock has no effect on Software Breakpoint Instruction debug events and Halting debug events.

H6.5.5 Debug behavior when the OS Lock is unlocked

When the OS Lock is unlocked, an OS Unlock Catch debug event is generated if EDECR.OUCE is set to 1. See *OS Unlock Catch debug event* on page H3-4751.

H6.5.6 Debug behavior when the OS Double Lock is locked

The OS Double Lock is locked immediately before a powerdown sequence. The OS Double Lock ensures that it is safe to remove core power by forcing the debug interfaces to be quiescent.

When `DoubleLockStatus()` == TRUE:

- The external debug interface only has restricted access to the debug registers, so that it is quiescent before removing power. See *External debug interface register access permissions summary* on page H8-4819.
- Debug exceptions, other than Software Breakpoint Instruction exceptions, are not generated.
- Halting is prohibited. See *Halting allowed and halting prohibited* on page H2-4695.

  Note

  Pending Halting debug events might be lost when core power is removed.
- No asynchronous debug events are `WFI` or `WFE` wake-up events.

Software must synchronize the update to OSDLR before it indicates to the system that core power can be removed. The interface between the PE and its power controller is IMPLEMENTATION DEFINED.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Typically software indicates that core power can be removed by entering the Wait For Interrupt state. This means that software must explicitly synchronize the OSDLR update before issuing the `WFI` instruction.

OSDLR.DLK is ignored and `DoubleLockStatus()` == FALSE if either:

- The PE is in Debug state.
- DBGPRCR.CORENPDRQ is set to 1.

Note

It is possible to enter Debug state with OSDLR.DLK set to 1. This is because a context synchronization operation is required to ensure the OS Double Lock is locked, meaning that Debug state might be entered before the OSDLR update is synchronized.

Because OSDLR.DLK is ignored when DBGPRCR.CORENPDRQ is set to 1, and an external debugger can write to DBGPRCR.CORENPDRQ, software must not rely on using the OS Double Lock to disable debug exceptions or to prohibit halting, or both. ARM deprecates use of the OS Double Lock for these purposes, and instead recommends that software:

- Uses the OS Lock to disable debug exceptions during save or restore sequences.
- Uses the debug authentication interface to prohibit halting and external debug access to debug registers at times other than immediately prior to removing power.

As the purpose of the OS Double Lock is to ensure that it is safe to remove core power, it is important to avoid race conditions that defeat this purpose. ARM recommends that:

- Once the write to OSDLR.DLK has been synchronized by a *Context synchronization operation* and `DoubleLockStatus()` == TRUE, a PE must:
  - Not allow a debug event generated before the *Context synchronization operation* to cause an entry to Debug state or act as a wake-up event for a `WFI` or `WFE` instruction after the context synchronization operation has completed.
  - Complete any external debug access started before the *Context synchronization operation* by the time the context synchronization operation completes.

    Note

    A debug register access might be in progress when software sets OSDLR.DLK to 1. An implementation must not permit the synchronization of locking the OS Double Lock to stall indefinitely while waiting for that access to complete. This means that any debug register access that is in progress when software sets OSDLR.DLK to 1 must complete or return an error in finite time.

- If a write to DBGPRCR or EDPRCR made when OSDLR.DLK == 1 changes DBGPRCR.CORENPDRQ or EDPRCR.CORENPDRQ from 1 to 0, meaning `DoubleLockStatus()` changes from FALSE to TRUE, then before signaling to the system that the CORENPDRQ field has been cleared and emulation of powerdown is no longer requested, meaning the system can remove core power, the PE must ensure that all the requirements for `DoubleLockStatus()` == TRUE listed in this section are met.

In the standard OS Save sequence, the OS Lock is locked before the OS Double Lock is locked. This means that writes to CORENPDRQ are ignored by the time the OS Double Lock is locked. However, if `DoubleLockStatus()` == FALSE, an external debugger can clear the OS Lock at any time, and then write to EDPRCR.

H6.6 Reset and debug

All registers in the Core power domain are reset either by a Warm reset or a Cold reset, as described in *Reset* on page D1-1447, including external debug logic registers.

All registers in the Debug power domain are reset by an External Debug reset.

Figure H6-2 shows this reset scheme. The following three reset signals are an example implementation of the reset scheme:

- **CORERESET**, which must be asserted for a Warm reset.
- **CPUPORESET**, which must be asserted for a Cold reset.
- **PRESETDBG**, which must be asserted for an External Debug reset.

As shown in the figure, the external debug logic is split between the Debug power domain and the Core power domain.

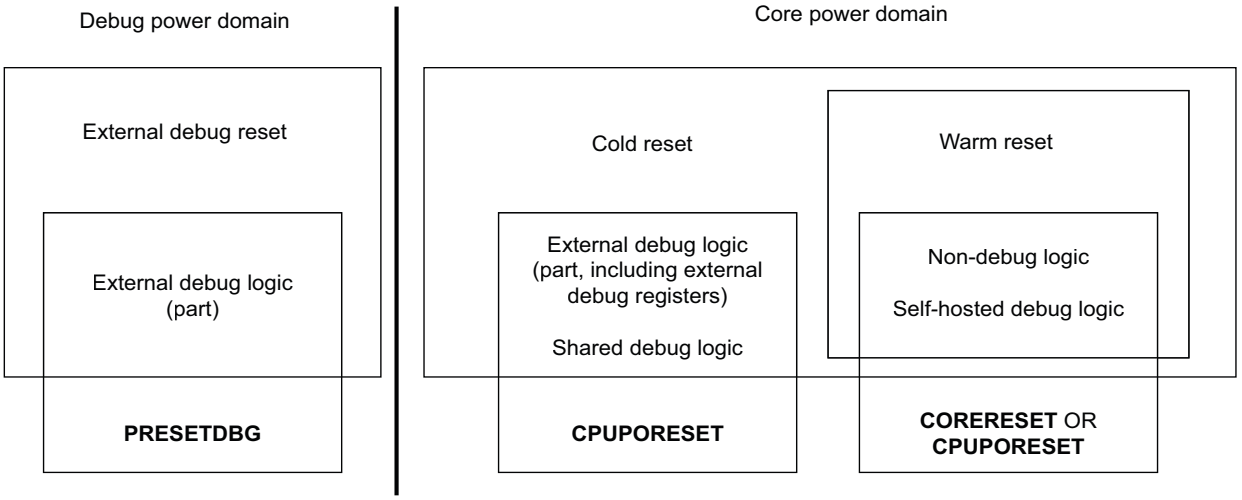

Figure H6-2 Power and reset domains

For more information about power domains and power states, see *Power domains and debug* on page H6-4793.

When power is first applied to the Debug power domain, **PRESETDBG** must be asserted.

When power is first applied to the Core power domain, **CPUPORESET** must be asserted.

Note

In this scheme, logic in the Warm reset domain is reset by asserting either **CORERESET** or **CPUPORESET**. This implies a particular implementation style that permits these approaches.

CPUPORESET is not normally asserted on moving from a low-power state, where power has not been removed, to a full-power state. This can occur, for example, on exiting a low-power retention state. See also *Emulating low-power states* on page H6-4796 and *EDPRSR, External Debug Processor Status Register* on page H9-4899.

H6.6.1 External debug interface accesses to registers in reset

If a reset signal is asserted and the external debug interface:

- Writes a register, or indirectly writes a register or register field as a side-effect of an access:
  - Then, if the register or register field is reset by that reset signal, it is CONSTRAINED UNPREDICTABLE whether the register or register field takes the reset value or the value written. The reset value might be UNKNOWN.
  - Otherwise the register or register field takes the value that is written.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- Reads a register, or indirectly reads a register or register field, as part of an access:
  - Then, if the register or register field is reset by that reset signal, the value returned in UNKNOWN.
  - Otherwise, the value of the register or register field is returned.

It is IMPLEMENTATION DEFINED whether any register can be accessed when External Debug reset is being asserted. The result of these accesses is IMPLEMENTATION DEFINED.

Chapter H7
The PC Sample-based Profiling Extension

This chapter describes the PC Sample-based Profiling Extension, that is an OPTIONAL extension to the ARMv8 architecture. The extension provides a non-invasive external debug component.

Note

This form of the PC Sample-based Profiling Extension is OPTIONAL. ARM recommends that if extension EDPCSR is not implemented that an alternative IMPLEMENTATION DEFINED form of Sample-based Profiling is implemented.

It contains the following section:

- *Sample-based profiling of the PC* on page H7-4806.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H7.1 Sample-based profiling of the PC

The PC Sample-based Profiling Extension is an OPTIONAL extension to the architecture. It provides a mechanism for coarse-grained profiling of software executing on the PE by an external debugger, without changing the behavior of that software. The following sections describe this extension:

- *The implemented Sample-based Profiling registers*.
- *Reads of the EDPCSRs*.
- *Reads of the EDVCSR* on page H7-4807.
- *Accuracy of sampling* on page H7-4807.
- *PC Sample-based Profiling and security* on page H7-4808.
- *Pseudocode description of PC Sample-based Profiling* on page H7-4808.

H7.1.1 The implemented Sample-based Profiling registers

An implementation that includes the Sample-based Profiling Extension implements the following external debug registers:

- EDPCSR is a 64-bit read-only register that contains a sampled program counter value. As external debug register accesses are atomic only at word granularity, EDPCSR is split into two registers: EDPCSRhi and EDPCSRlo. See *Reads of the EDPCSRs*.
- EDCIDSR is a read-only register that contains the sampled value of CONTEXTIDR_EL1 indirectly read on reading EDPCSRlo.

  Note

  If EL3 is implemented and using AArch32, then CONTEXTIDR is a Banked register and EDCIDSR samples the current Banked copy of CONTEXTIDR.

- EDVIDSR is a read-only register that contains sampled values captured on reading EDPSRlo. If neither EL3 nor EL2 are implemented, EDVIDSR is not implemented.

H7.1.2 Reads of the EDPCSRs

A read of the EDPCSRlo normally has the side-effect of indirectly writing to EDCIDSR, EDVIDSR, and EDPCSRhi. When EDPCSRlo is read, the bottom 32 bits of a program counter sample are returned. The top 32 bits are captured in EDPCSRhi and can be read later. However:

- If the PE is in Debug state, or Sample-based Profiling is prohibited, EDPCSRlo reads as `0xFFFFFFFF` and EDCIDSR, EDVIDSR, and EDPCSRhi become UNKNOWN. See *PC Sample-based Profiling and security* on page H7-4808.
- If the PE is in Reset state, the sampled value is UNKNOWN, and EDCIDSR, EDVIDSR, and EDPCSRhi become UNKNOWN.
- If no instruction has been retired since the PE left Reset state, Debug state, or a state where Sample-based Profiling is prohibited, the sampled value is UNKNOWN and EDCIDSR, EDVIDSR, and EDPCSRhi become UNKNOWN.
- The indirect writes to EDCIDSR, EDVIDSR, and EDPCSRhi might not occur for a memory-mapped access to the external debug interface. For more information, see *Memory-mapped accesses to the external debug interface* on page H8-4816.

The value written to EDCIDSR is an indirect read of CONTEXTIDR_EL1. This means that it is CONSTRAINED UNPREDICTABLE whether EDCIDSR is set to the original or new value if a read of the EDPCSRlo samples:

- An instruction that writes to CONTEXTIDR_EL1.
- The next context synchronization operation.
- Any instruction executed between these two instructions.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Note

In the ARMv7 PC Sample-based Profiling Extension, an offset was applied to the sampled program counter value and this offset and the instruction set state indicated in bits [1:0] of the sampled value. In the ARMv8 PC Sample-based Profiling Extension, the sampled value is the address of an instruction that has executed, with no offset and no indication of the instruction set state.

H7.1.3 Reads of the EDVCSR

A read of the EDVIDSR contains sampled values captured on reading EDPSRlo, where:

- EDVIDSR.NS indicates the Security state associated with the most recent EDPCSR sample.
- EDVIDSR.E2 indicates whether the most recent EDPCSR sample was associated with EL2. If EDVIDSR.NS == 0, this bit is 0.
- EDVIDSR.E3 indicates whether the most recent EDPCSR sample was associated with EL3 using AArch64. If EDVIDSR.NS == 1 or the PE was in AArch32 state when EDPCSRlo was read, this bit is 0.
- EDVIDSR.HV indicates whether EDPCSRhi is valid, that is, bits [63:32] of the most recent program counter sample are nonzero.

  Note

  — EDVIDSR.HV == 1 does not mean that EDPCSRhi != 0. EDVIDSR.HV == 0 is a hint that EDPCSRhi does not need to be read.

  — Tools must take care to avoid skewing sampled data by over-sampling code for which EDVIDSR.HV == 0.

- EDVIDSR.VMID indicates the value of the VTTBR_EL2.VMID register associated with the most recent EDPCSRlo sample. If EDVIDSR.NS == 0 or EDVIDSR.E2 == 1, this field is RAZ.

If EL2 is not implemented, EDVIDSR.E2 and EDVIDSR.VMID are RES0.

If EL3 is not implemented, EDVIDSR.E3 is RES0, and EDVIDSR.NS has a fixed read-only value.

H7.1.4 Accuracy of sampling

PC Sample-based Profiling is provided as a mechanism for tools to populate a statistical model of the performance of software executing on the PE. The statistical data returned by random sampling of EDPCSR, EDCIDSR, and EDVIDSR must allow such statistical modeling.

It must be possible to sample references to branch targets. It is IMPLEMENTATION DEFINED whether references to other instructions can be sampled. The branch target for a conditional branch instruction that fails its condition check is the instruction that follows the conditional branch instruction. The branch target for an exception is the exception vector address.

Under normal operating conditions, the whole sample, EDPCSR, EDCIDSR, and EDVIDSR, must reference an instruction that was committed for execution, including its context, and must not reference instructions that are fetched but not committed for execution.

To keep the implementation and validation cost low, a reasonable degree of inaccuracy in the sampled data is acceptable. ARM does not define *a reasonable degree of inaccuracy* but recommends the following guidelines:

- In exceptional circumstances, such as a change in Security state or other boundary condition, it is acceptable for the sample to represent an instruction that was not committed for execution.
- Under very unusual non-repeating pathological cases the sample can represent an instruction that was not committed for execution. These cases are likely to occur as a result of asynchronous exceptions, such as interrupts, where the chance of a systematic error in sampling is very unlikely.

See also *Non-invasive behavior* on page D5-1752.

Non-Confidential - Beta

H7.1.5 PC Sample-based Profiling and security

PC Sample-based Profiling is a non-invasive external debug component, which is controlled by an IMPLEMENTATION DEFINED authentication interface. PC Sample-based Profiling is prohibited unless both:

- Allowed by the IMPLEMENTATION DEFINED authentication interface `ExternalNoninvasiveDebugEnabled()`.
- Any one of:
  - Executing in Non-secure state.
  - EL3 is not implemented.
  - EL3 is implemented, executing in Secure state, and allowed by the IMPLEMENTATION DEFINED authentication interface `ExternalSecureNoninvasiveDebugEnabled()`.
  - EL3 is implemented, EL3 or EL1 is using AArch32, executing at EL0 in Secure state, and SDER32_EL3.SUNIDEN == 1.

The pseudocode function `ExternalNoninvasiveDebugAllowed()` indicates when PC Sample-based Profiling is allowed.

The state of implementation defined authentication interface is visible through DBGAUTHSTATUS_EL1.

See also Appendix K2 *Recommended External Debug Interface*.

H7.1.6 Pseudocode description of PC Sample-based Profiling

PC Sample-based Profiling is described by the pseudocode functions:

- `CreatePCSample()`, which populates a variable of type `PCSample`.
- `EDPCSRlo[]`. which writes a PC sample to the EDPSCR and associated registers.

Chapter H8
About the External Debug Registers

This chapter provides some additional information about the external debug registers. It contains the following sections:

- *Relationship between external debug and System registers* on page H8-4810.
- *Supported access sizes* on page H8-4811.
- *Synchronization of changes to the external debug registers* on page H8-4812.
- *Memory-mapped accesses to the external debug interface* on page H8-4816.
- *External debug interface register access permissions* on page H8-4818.
- *External debug interface registers* on page H8-4822.
- *Cross-trigger interface registers* on page H8-4827.
- *External debug register resets* on page H8-4829.

Note

Where necessary Table K13-1 on page K13-5568 disambiguates the general register references used in this chapter.

Non-Confidential - Beta

H8.2 Supported access sizes

The memory access sizes supported by any peripheral is IMPLEMENTATION DEFINED by the peripheral. For accesses to the debug registers, Performance Monitor registers, and CTI registers, implementations must support:

- Word-aligned 32-bit accesses to access 32-bit registers or either half of a 64-bit register mapped to a doubleword-aligned pair of adjacent 32-bit locations.
- Doubleword-aligned 64-bit accesses to access 64-bit registers mapped to a doubleword-aligned pair of adjacent 32-bit locations.

Note

This means that a system implementing the debug registers using a 32-bit bus, such as a AMBA APB3, with a wider system interconnect must implement a bridge between the system and the debug bus that can split 64-bit accesses.

All registers are only single-copy atomic at word granularity. This means that for 64-bit accesses to a 64-bit register, the system might generate a pair of 32-bit accesses. The order in which the two halves are accessed is not specified.

The following accesses are not supported:

- Byte.
- Halfword.
- Unaligned word. These accesses are not word single-copy atomic.
- Unaligned doubleword. These accesses are not doubleword single-copy atomic.
- Doubleword accesses to a pair of 32-bit locations that are not a doubleword-aligned pair forming a 64-bit register.
- Quadword or higher.
- Exclusive accesses.

For each of these access types, it is CONSTRAINED UNPREDICTABLE whether:

- The access generates an external abort or not.
- The defined side-effects of a read occur or not. A read returns UNKNOWN data.
- A write is ignored or sets the accessed register or registers to UNKNOWN.

For accesses from the external debug interface, the size of an access is determined by the interface. For an access from an ADIv5-compliant Memory Access Port, MEM-AP, this is specified by the MEM-AP CSW register.

See *Access sizes for memory-mapped accesses* on page H8-4817.

Non-Confidential - Beta

H8.3 Synchronization of changes to the external debug registers

This section describes the synchronization requirements for the external debug interface.

For more information on how these requirements affect debug, see:

- *Synchronization and debug exceptions* on page D2-1612 for exceptions taken from AArch64 state, or *Synchronization and debug exceptions* on page G2-3837 for exceptions taken from AArch32 state.
- *Synchronization and Halting debug events* on page H3-4754.
- *Synchronization of DCC and ITR accesses* on page H4-4768.

This section refers to accesses from the external debug interface as external reads and external writes. It refers to accesses to System registers as direct reads, direct writes, indirect reads, and indirect writes.

Note

Synchronization requirements for AArch64 System registers on page D7-1802 defines direct read, direct write, indirect read, and indirect write, and classifies external reads as indirect reads, and external writes as indirect writes.

Writes to the same register are serialized, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes. With the exception of DBGBCR<n>_EL1, DBGBVR<n>_EL1, DBGWCR<n>_EL1, and DBGWVR<n>_EL1, external writes to different registers are not necessarily observed in the same order by all observers as the order in which they complete.

Synchronization of DCC and ITR accesses on page H4-4768 describes the synchronization requirements for the DCC and ITR.

Changes to the IMPLEMENTATION DEFINED authentication interface are external writes to the authentication status registers by the master of the authentication interface. See *Synchronization and the authentication interface* on page H8-4814.

Explicit synchronization is not required for an external read or an external write by an external agent to be observable to a following external read or external write by that agent to the same register using the same address, and so is never required for registers that are accessible only in the external debug interface.

Some registers are guaranteed to be observable to all observers in finite time, without explicit synchronization. For more information, see *Synchronization requirements for AArch64 System registers* on page D7-1802 or *Synchronization of changes to AArch32 System registers* on page G4-4015. Otherwise, explicit synchronization is normally required following an external write to any register for that write to be observable by:

- A direct access.
- An indirect read by an instruction.
- An external read of the register using a different address.

This means that an external write by an external agent is guaranteed to have an effect on subsequent instructions executed by the PE only if all of the following are true:

- The write has completed.
- The PE has executed a context synchronization operation.
- The context synchronization operation was executed after the write completed.

The order and synchronization of direct reads and direct writes of System registers is defined by *Synchronization requirements for AArch64 System registers* on page D7-1802.

The external agent must be able to guarantee completion of a write. For example by:

- Marking the memory as Device-nGnRnE and executing a `DSB` barrier, if the system supports this property.
- Reading back the value written.
- Some guaranteed property of the connection between the PE and the external agent.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Note

For an external Debug Access Port, this is an IMPLEMENTATION DEFINED property. For a CoreSight system using APB-AP to access a debug APB, a write is guaranteed to complete before the APB-AP allows a second APB transaction to complete.

The external agent and PE can guarantee ordering by, for example, passing messages in an ordered way with respect to the external write and the context synchronization operation, and relying on the memory ordering rules provided by the memory model.

External reads and external writes complete in the order in which they arrive at the PE. For accesses to different register locations the external agent must create this order by:

- Marking the memory as Device-nGnRnE or Device-nGnRE.
- Using the appropriate memory barriers.
- Some guaranteed property of the connection between the PE and the external agent.

Note

For an external Debug Access Port, this is an IMPLEMENTATION DEFINED property. For a CoreSight system using APB-AP to access a debug APB, accesses complete in order.

However, the external agent cannot force synchronization of completed writes without halting the PE. Executing an `ISB` instruction, either in Debug state or in Non-debug state, and exiting from Debug state forces synchronization. If the PE is in Debug state, executing an `ISB` instruction is guaranteed to explicitly synchronize any external reads, external writes, and changes to the authentication interface that are ordered before the external write to EDITR.

For any given observer, external writes to the following register groups are guaranteed to be observable in the same order in which they complete:

- The breakpoint registers, DBGBCR<n>_EL1 and DBGBVR<n>_EL1.
- The watchpoint registers, DBGWCR<n>_EL1 and DBGWVR<n>_EL1.

This guarantee only applies to external writes to registers within one of these groups. There is no guarantee regarding the ordering of the observability of external writes within these groups with respect to external writes to registers, for example EDSCR, or between breakpoints and watchpoints, including watchpoints linked to context matching breakpoints.

Note

This means that a debugger can rely on the external writes to be observed in the same order in which they complete. It does not mean that a debugger can rely on the external writes being observed in finite time.

In a simple sequential execution an indirect write that occurs as a side-effect of an access happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect.

If two or more interfaces simultaneously access a register, the behavior must be as if the accesses occurred atomically and in any order. This is described in *Examples of the synchronization of changes to the external debug registers* on page H8-4814.

Some registers have the property that for certain bits a write of 0 is ignored and a write of 1 has an effect. This means that simultaneous writes must be merged. Registers that have this property and support both external debug and System register access include DBGCLAIMSET_EL1, DBGCLAIMCLR_EL1, PMCR_EL0.{C,P}, PMOVSSET_EL0, PMOVSCLR_EL0, PMCNTENSET_EL0, PMCNTENCLR_EL0, PMINTENSET_EL1, PMINTENCLR_EL1, and PMSWINC_EL0. This last register is OPTIONAL and deprecated in the external debug interface.

Non-Confidential - Beta

H8.3.1 Synchronization and the authentication interface

Changes to the authentication interface are indirect writes to the Authentication Status registers by the master of the authentication interface. For each of these Authentication Status registers, it is IMPLEMENTATION DEFINED whether a change on the authentication interface is guaranteed to be observable to an external debug interface read of the register only after a context synchronization operation or in finite time.

For DBGAUTHSTATUS_EL1, a change on the authentication interface is guaranteed to be observable to a System register read of DBGAUTHSTATUS_EL1 only after a context synchronization operation.

H8.3.2 Examples of the synchronization of changes to the external debug registers

Example H8-1, Example H8-2, and Example H8-3 on page H8-4815 show the synchronization of changes to the external debug registers.

Example H8-1 Order of synchronization of Breakpoint and Watchpoint register writes

Initially DBGBVR<n>_EL1 is `0x8000` and DBGBCR<n>_EL1 is `0x0181`. This means that a breakpoint is enabled on the halfword T32 instruction at address `0x8000`.

A sequence of external writes occurs in the following order:

1. `0x0000` is written to DBGBCR<n>_EL1, disabling the breakpoint.
2. `0x9000` is written to DBGBVR<n>_EL1[31:0].
3. `0x0061` is written to DBGBCR<n>_EL1, enabling a breakpoint on the halfword at address `0x9002`.

The external writes must be observable to indirect reads in the same order as the external writes complete. This means that at no point is there a breakpoint enabled on either of the halfwords at address `0x8002` and `0x9000`.

Similarly a breakpoint or watchpoint must be disabled:

- If both halves of a 64-bit address have to be updated.
- If any of the DBGBCR<n>_EL1 or DBGWCR<n>_EL1 fields are modified at the same time as updating the address.

Example H8-2 Simultaneous accesses to DTR registers

Initially EDSCR.{TXfull, TXU, ERR} are 0. Then:

- `0x0DCCDA7A` is directly written to DBGDTRTX_EL0 by an `MSR` instruction.
- DBGDTRTX_EL0 is indirectly read by the external debug interface.

These accesses might happen at the same time and in any order.

If the direct write of `0x0DCCDA7A` to DBGDTRTX_EL0 is handled first, then:

- The external debug interface read of DBGDTRTX_EL0 clears EDSCR.TXfull to 0.
- EDSCR.{TXU, ERR} are unchanged.
- The external debug interface read returns `0x0DCCDA7A`.

If the indirect read of DBGDTRTX_EL0 by the external debug interface is handled first, then:

- The external debug interface read of DBGDTRTX_EL0 causes an underrun and as a result EDSCR.{TXU, ERR} are both set to 1.
- The external debug interface returns an UNKNOWN value.
- Writing `0x0DCCDA7A` to DBGDTRTX_EL0 sets DTRTX to `0x0DCCDA7A` and EDSCR.TXfull to 1.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Example H8-3 Simultaneous writes to CLAIM registers

Initially all CLAIM tag bits are 0. Then:

- `0x01` is written to DBGCLAIMSET_EL1 by a direct write, followed by an explicit context synchronization operation.
- `0x02` is written to DBGCLAIMSET_EL1 by an external write.

These events might happen at the same time and in either order.

After this:

- DBGCLAIMCLR_EL1 is read by a direct read.
- DBGCLAIMCLR_EL1 is read by an external read.

In this case, a direct read can return either `0x01` or `0x03`, and the external read can return either `0x02` or `0x03`.

The only permitted final result for the CLAIM tags is the value `0x03`, because this would be the result regardless of whether `0x01` or `0x02` is written first. This is because the external write is guaranteed to be observable to a direct read in finite time. See *Synchronization requirements for AArch64 System registers* on page D7-1802.

It is not possible for a direct read to return `0x01` and the external read to return `0x02`, because the writes to DBGCLAIMCLR_EL1 are serialized.

In the following scenario, there is only one permitted result. Both observers observe the value `0x03`, and then, at the same time, two writes occur:

- `0x04` is written to DBGCLAIMSET_EL1 by a direct write, followed by an explicit context synchronization operation.
- `0x01` is written to DBGCLAIMCLR_EL1 by an external write.

In this case only permitted final result for the CLAIM tags is the value `0x06`.

H8.4 Memory-mapped accesses to the external debug interface

Support for memory-mapped access to the external debug interface is OPTIONAL.

If the external debug interface is CoreSight compliant, then an OPTIONAL Software Lock can be implemented for memory-mapped accesses to each component. The Software Locks are controlled by EDLSR and EDLAR, PMLSR and PMLAR, and CTILSR and CTILAR. See *Management registers and CoreSight compliance* on page K2-5387.

With the exception of these registers and the effect of the Software Lock, the behavior of the memory-mapped accesses is the same as for other accesses to the external debug interface.

Note

The recommended memory-mapped accesses to the external debug interface are not compatible with the memory-mapped interface defined in ARMv7. In particular:

- The memory map is different.
- Memory-mapped accesses do not behave differently to Debug Access Port accesses when OSLSR.OSLK == 1, meaning that the OS Lock is locked.

H8.4.1 Register access permissions for memory-mapped accesses

It is IMPLEMENTATION DEFINED whether unprivileged memory-mapped accesses are allowed. Privileged software is responsible for controlling memory-mapped accesses using the MMU.

If memory-mapped accesses are made through an ADIv5 interface, the Debug Access Port can block the access using **DBGSWENABLE**. This is outside the scope of the ARMv8-A architecture. See *ARM® Debug Interface Architecture Specification ADIv5.0 to ADIv5.2*.

Effect of the OPTIONAL Software Lock on memory-mapped access

For memory-mapped accesses, if other controls permit access to a register, the OPTIONAL Software Lock is implemented, and EDLSR.SLK, PMLSR.SLK, or CTILSR.SLK is set to 1, meaning the Software Lock is locked, then with the exception of the LAR itself:

- If other controls permit access to a register, then writes are ignored. That is:
  - Read/write (RW) registers become read-only (RO).
  - Write-only (WO) registers become write-ignored (WI).
- Reads and writes have no side-effects. A side-effect is where a direct read or a direct write of a register creates an indirect write of the same or another register. When the Software Lock is locked, the indirect write does not occur.
- Writes to EDLAR, PMLAR, and CTILAR are unaffected.

This behavior must also apply to all IMPLEMENTATION DEFINED registers.

For example, if EDLSR.SLK is set to 1:

- EDSCR.{TXfull, TXU, ERR} are unchanged by a memory-mapped read from DBGDTRTX_EL0.
- EDSCR.{RXfull, RXO, ERR} are unchanged by a memory-mapped write to DBGDTRRX_EL0 that is ignored.
- EDSCR.{ITE, ITO, ERR} are unchanged by a memory-mapped write to EDITR that is ignored.
- OSLSR.OSLK is unchanged by a memory-mapped write to OSLAR_EL1 that is ignored.
- EDPCSR[63:32], EDCIDSR, and EDVIDSR are unchanged by a memory-mapped read from EDPCSR[31:0].

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Note

Updating EDVIDSR, EDCIDSR, and EDPCSRhi are side-effects of reading EDPCSRlo, such that these registers contain the matching context for EDPCSRlo. The process that updates EDPCSRlo with PC samples is not a side-effect of the access. Reads of EDPCSRlo made when the Software Lock is locked can be used to profile software.

- EDPRSR.{SDR, SPMAD, SDAD, SR, SPD} are unchanged by a memory-mapped read from EDPRSR.
- EDPRSR.SDAD is not set if an error response is returned due to a memory-mapped read or write of any debug register as the result of the value of the EDAD field.
- The CLAIM tags are unchanged by memory-mapped writes to DBGCLAIMSET_EL1 and DBGCLAIMCLR_EL1 which are ignored.

Similarly, if PMLSR.SLK is set to 1, then EDPRSR.SPMAD is not set if an error response is returned to a memory-mapped read or write of any Performance Monitors register due to the value of the EPMAD field.

Behavior of a not permitted memory-mapped access

Where the architecture requires that an external debug interface access generates an error response, a memory-mapped access must also generate an error response. However, it is IMPLEMENTATION DEFINED how the error response is handled, as this depends on the system.

ARM recommends that the error is returned as either:

- A synchronous external Data Abort.
- An SError interrupt.

H8.4.2 Synchronization of memory-mapped accesses to external debug registers

The synchronization requirements for memory-mapped accesses to the external debug interface is described in *Synchronization of changes to the external debug registers* on page H8-4812.

The synchronization requirements between different routes to the external debug interface, that is, between Debug Access Port accesses and memory-mapped accesses are IMPLEMENTATION DEFINED.

H8.4.3 Access sizes for memory-mapped accesses

For memory-mapped accesses from a PE that complies with an ARM architecture, the single-copy atomicity rules for the instruction, the type of instruction, and the type of memory accessed, determine the size of the access made by an instruction. Example H8-4 shows this.

Example H8-4 Access sizes for memory-mapped accesses

Two Load Doubleword instructions made to consecutive doubleword-aligned locations generate a pair of single-copy atomic doubleword reads. However, if the accesses are made to Normal memory or Device-GRE memory they might appear as a single quadword access that is not supported by the peripheral.

ARMv8 does not require the size of each element accessed by a multi-register load or store instruction to be identifiable by the memory system beyond the PE. Any memory-mapped access to a debug register is defined to be beyond the PE.

Software must use a Device-nGRE or stronger memory-type and use only single register load and store instructions to create memory accesses that are supported by the peripheral. For more information, see *Memory types and attributes* on page B2-93.

Non-Confidential - Beta

H8.5 External debug interface register access permissions

Some external accesses to debug registers and Performance Monitor registers are not permitted and return an error response if:

- The Core power domain is powered down or is in low-power state where the registers cannot be accessed.
- OSLSR.OSLK == 1. The OS Lock is locked.
- `DoubleLockStatus()` == TRUE. The OS Double Lock is locked.
- Access by the external debug interface is disabled by the authentication interface or secure monitor.

Not all registers are affected in all of these cases. For details, see *External debug interface register access permissions summary* on page H8-4819.

Note

OSLSR.OSLK is visible through EDPRSR.

H8.5.1 External debug over powerdown and locks

Accessing registers using the external debug interface is not possible when the Debug power domain is off. In this case all accesses return an error.

External accesses to debug and Performance Monitors registers in the Core power domain are not permitted and return an error response if:

- The Core power domain is off or in low-power state where the registers cannot be accessed.
- OSLSR.OSLK == 1, meaning that the OS Lock is locked. This allows software to prevent external debugger modification of the registers while it saves and restores them over powerdown.

  Note

  In this case OSLAR_EL1 can be accessed, meaning an external debugger can override this lock.

- `DoubleLockStatus()` == TRUE. This means that the OS Double Lock is locked. The OS Double Lock ensures that it is safe to remove Core power by forcing the debug interface to be quiescent.

See also *Debug registers to save over powerdown* on page H6-4798.

H8.5.2 External access disabled

Accesses are further controlled by the external authentication interface. An untrusted external debugger cannot program the breakpoint and watchpoint registers to generate spurious debug exceptions. If external invasive debugging is not enabled, these external accesses to the registers are disabled. If EL3 is implemented, then SDCR provides additional external access disable controls for those registers if Secure external invasive debugging is disabled.

The disable applies to:

- *DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 15* on page H9-4839.
- *DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 15* on page H9-4836.
- *DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 15* on page H9-4853.
- *DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15* on page H9-4850.

The external debug interface cannot access these registers if either:

- External debugging is not enabled. `ExternalInvasiveDebugEnabled()` == FALSE.
- Secure external debugging is not enabled, meaning `ExternalSecureInvasiveDebugEnabled()` == FALSE, and any of the following:
  - EL3 is not implemented and the implemented Security state is Secure state.
  - EL3 is implemented and SDCR.EDAD == 1.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

The AllowExternalDebugAccess() pseudocode function describes these accessibility rules.

PEs might also provide an OPTIONAL external debug interface to the Performance Monitor registers. The authentication interface and SDCR provide similar external access disable controls for those registers.

The external debug interface cannot access the Performance Monitor registers if either:

- External non-invasive debug is not enabled. ExternalNoninvasiveDebugEnabled() == FALSE.
- Secure external non-invasive debugging is not enabled, ExternalSecureNoninvasiveDebugEnabled() == FALSE, and any of:
  - EL3 is not implemented and the implemented Security state is Secure state.
  - EL3 is implemented and SDCR.EPMAD == 1.

The AllowExternalPMUAccess() pseudocode function describes these accessibility rules.

Note

- ARM recommends that secure software that is not making use of debug hardware does not lock out the external debug interface.
- ARMv8-A does not provide the equivalent control over access to Trace extension registers.

H8.5.3 Behavior of a not permitted access

For an external debug interface access by a Debug Access Port, the Debug Access Port receives the error response and must signal this to the external debugger. For an ADIv5 implementation of a Debug Access Port, the error sets a sticky error flag in the Debug Access Port that the debugger can poll, and that suppresses further accesses until it is explicitly cleared.

When an error is returned because external access is disabled, and this is the highest priority error condition, a sticky error flag in EDPRSR is indirectly written to 1 as a side-effect of the access:

- For a debug register access when AllowExternalDebugAccess() == FALSE, EDPRSR.SDAD is indirectly written to 1.
- For Performance Monitor register access when AllowExternalPMUAccess() == FALSE, EDPRSR.SPMAD is indirectly written to 1.

The indirect write might not occur for a memory-mapped access to the external debug interface. For more information, see *Register access permissions for memory-mapped accesses* on page H8-4816.

If no error is returned, or the error is returned because of a higher priority error condition, the flag in EDPRSR is unchanged.

See also *Behavior of a not permitted memory-mapped access* on page H8-4817.

For more information, see *ARM® Debug Interface Architecture Specification*.

H8.5.4 Trapping software access to debug registers

When EDSCR.TDA == 1, software access to the breakpoint and watchpoint registers generate a Halting debug event and entry to Debug state. For more information see *Software Access debug event* on page H3-4753.

H8.5.5 External debug interface register access permissions summary

For accesses to:

- IMPLEMENTATION DEFINED registers, see *IMPLEMENTATION DEFINED registers* on page H8-4820.
- OPTIONAL registers for CoreSight compliance, see *OPTIONAL CoreSight management registers* on page H8-4820.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- Reserved, unallocated, or unimplemented registers, writes to read-only registers, and reads of write-only registers, see *Reserved and unallocated registers*.

For all other external debug interface, CTI, and Performance Monitor registers, Table H8-3 on page H8-4825, Table H8-4 on page H8-4827 and Table I2-1 on page I2-4979, show the response of the PE to accesses by the external debug interface.

H8.5.6 IMPLEMENTATION DEFINED registers

For debug registers, Performance Monitors registers, CTI registers, IMPLEMENTATION DEFINED register access permissions are IMPLEMENTATION DEFINED. The power domain in which these registers are implemented is also IMPLEMENTATION DEFINED.

If OPTIONAL memory-mapped access to the external debug interface is supported, there are additional constraints on memory-mapped accesses to registers. These constraints must also apply to IMPLEMENTATION DEFINED registers. In particular, if the OPTIONAL Software Lock is locked, writes are ignored and accesses have no side-effects. For more information see *Register access permissions for memory-mapped accesses* on page H8-4816.

H8.5.7 OPTIONAL CoreSight management registers

Compliance with CoreSight architecture requires additional registers in the range `0xF00 - 0xFFC` that are always accessible. See *Management registers and CoreSight compliance* on page K2-5387.

H8.5.8 Reserved and unallocated registers

The following information relates to certain types of reserved accesses:

- Reads and writes of unallocated locations. These accesses are reserved for the architecture.
- Reads and writes of locations for features that are not implemented, including:
  - OPTIONAL features that are not implemented.
  - Breakpoints and watchpoints that are not implemented.
  - Performance Monitors counters that are not implemented.
  - CTI triggers that are not implemented.

  These accesses are reserved.
- Reads of WO locations. These accesses are reserved for the architecture.
- Writes to RO locations. These accesses are reserved for the architecture.

Reserved accesses normally RAZ/WI. However, software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

Note

Reads of WO and writes to RO refers to the default access permissions for a register. For example, when the SLK field is set, meaning that the relevant registers become RO, a memory-mapped write to a RW register is ignored, and not treated as a reserved access.

The following reserved registers are RES0 in all conditions, other than when debug power is off:

- If the implementation is CoreSight architecture compliant, all reserved registers in the range `0xF00 - 0xFFC`. See *Management register access permissions* on page K2-5388.
- All unallocated Processor ID Registers. That is, unallocated debug registers in the range `0xD00-0xDFC`.
- All reserved CTI registers.

Otherwise, the architecture defines that:

1. If debug power is off, all register accesses, including reserved accesses, return an error.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

2. For reserved debug registers and Performance Monitors registers, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0, when any of the following hold:

   Off The Core power domain is either completely off or in a low-power state in which the Core power domain registers cannot be accessed.

   DLK `DoubleLockStatus()` == TRUE. The OS Double Lock is locked.

   OSLK OSLSR.OSLK == 1. The OS Lock is locked.

3. In addition, for reserved debug registers in the address ranges `0x400 - 0x4FC` and `0x800 - 0x8FC`, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when conditions 1 or 2 do not apply and:

   EDAD `AllowExternalDebugAccess()` == FALSE. External debug is disabled.

   Note

   See also *Behavior of a not permitted access* on page H8-4819.

4. In addition, for reserved Performance Monitors registers in the address ranges `0x000 - 0x0FC` and `0x400 - 0x47C`, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when conditions 1 or 2 do not apply and:

   EPMAD `AllowExternalPMUAccess()` == FALSE. External Performance Monitor access is disabled.

   Note

   See also *Behavior of a not permitted access* on page H8-4819.

H8.6.1 Access permissions for the External debug interface registers

Table H8-3 on page H8-4825 shows the access permissions for the external debug interface registers in an ARMv8-A Debug implementation. The terms are defined as follows:

Domain This describes the power domain in which the register is logically implemented. Registers described as implemented in the Core power domain might be implemented in the Debug power domain, as long as they exhibit the required behavior.

Conditions This lists the conditions under which the access is attempted.

To determine the access permissions for a register, read these columns from left to right, and stop at first column which lists the condition as being true.

The conditions are:

Off EDPRSR.PU == 0. The Core power domain is completely off, or in low-power state. In these cases the Core power domain registers cannot be accessed.

Note

If debug power is off, then all external debug interface accesses return an error.

DLK `DoubleLockStatus()` == TRUE. The OS Double Lock is locked.

OSLK OSLSR.OSLK == 1. The OS Lock is locked.

EDAD `AllowExternalDebugAccess()` == FALSE. External debug access is disabled. See also *Behavior of a not permitted access* on page H8-4819.

EPMAD `AllowExternalPMUAccess()` == FALSE. Access to the external Performance Monitors is disabled. See also *Behavior of a not permitted access* on page H8-4819.

Default This provides the default access permissions, if there are no conditions that prevent access to the register.

SLK This provides the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked. See *Register access permissions for memory-mapped accesses* on page H8-4816. For all other accesses, this column is ignored.

The access permissions are:

- This means that the default access permission applies. See the Default column, or the SLK column, if applicable.

RO This means that the register or field is read-only.

RW This means that the register or field is read/write. Individual fields within the register might be RO. See the relevant register description for details.

RC This means that the bit clears to 0 after a read.

(SE) This means that accesses to this register have indirect write side-effects. A side-effect occurs when a direct read or a direct write of a register creates an indirect write to the same register or to another register.

WO This means that the register or field is write-only.

WI This means that the register or field ignores writes.

IMP DEF This means that the access permissions are IMPLEMENTATION DEFINED.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

If OPTIONAL memory-mapped access to the external debug interface is supported, there might be additional constraints on memory-mapped accesses. See *Register access permissions for memory-mapped accesses* on page H8-4816.

Table H8-3 Access permissions for the external debug interface registers

			Conditions (priority from left to right)					
Offset	**Register**	**Domain**	**Off**	**DLK**	**OSLK**	**EDAD**	**Default**	**SLK**

H8.7 Cross-trigger interface registers

The embedded Cross-trigger Interface, CTI, is located within its own block of the external debug memory map. There must be one such block for each PE.

If the CTI of a PE does not implement the CTIDEVAFF0 or CTIDEVAFF1 registers it must be located 64KB above the debug registers in the external debug interface.

Table H8-4 shows the CTI register map.

Table H8-4 Cross-trigger interface map

H8.8 External debug register resets

Each register or field has a defined reset domain:

- Registers and fields in the Warm reset domain are also reset by a Cold reset and unchanged by an External Debug reset that is not coincident with a Cold reset or a Warm reset.
- Registers and fields in the Cold reset domain are unchanged by a Warm reset or an External Debug reset that is not coincident with a Cold reset.
- Registers and fields in the External Debug reset domain are unchanged by a Cold reset or a Warm reset that is not coincident with an External Debug reset.

Table H8-6 and Table H8-7 on page H8-4830 show the external debug register and CTI register resets. For other debug registers and Performance Monitors registers, see *Management register resets* on page K2-5392 and *Power domains and Performance Monitors registers reset* on page I2-4980.

Note

By reference to Figure H6-2 on page H6-4802 the power domain can be deduced from the reset domain. Table K2-7 on page K2-5392 also shows reset power domains.

Table H8-6 and Table H8-7 on page H8-4830 do not include:

- Read-only identification registers, such as Processor ID Registers and PMCFGR, that have a fixed value from reset.
- Read-only status registers, such as EDSCR.RW, that are evaluated each time the register is read and that have no meaningful reset value.
- Write-only registers, such as EDRCR, that only have an effect on writes, and have no meaningful reset value.
- Read/write registers, such as breakpoint and watchpoint registers, and EDPRCR.CORENPDRQ, that alias other registers. The reset values are described by the descriptions of those other registers.
- IMPLEMENTATION DEFINED registers. The reset values and reset domains of these registers are also IMPLEMENTATION DEFINED and might be UNKNOWN.

All other fields in the registers are set to an IMPLEMENTATION DEFINED value, that can be UNKNOWN. The register is in the specified reset domain.

Note

An IMPLEMENTATION DEFINED reset value, which can be UNKNOWN, means that hardware is not required to reset the register on the specified reset, but software must not rely on the register being preserved over reset.

Table H8-6 Summary of external debug register resets, debug registers

Register	Reset domain	Field	Value	Description
EDESR	Warm	SS	EDECR.SS	Halting Step debug event pending
		RC	EDECR.RCE	Reset Catch debug event pending
		OSUC	0	OS Unlock Catch debug event pending
EDECR	External debug	SS	0	Halting Step debug event enable
		RCE	0	Reset Catch debug event enable
		OSUCE	0	OS Unlock Catch debug event enable

Table H8-6 Summary of external debug register resets, debug registers (continued)

Register	Reset domain	Field	Value	Description
EDWAR	Cold	-	-	All fields
EDSCR	Cold	RXfull	0	DTRRX register full
		TXfull	0	DTRTX register full
		RXO	0	DTRRX overrun
		TXU	0	DTRTX underrun
		INTdis	0	Interrupt disable
		TDA	0	Trap debug register accesses to Debug state
		MA	0	Memory access mode in Debug state
		HDE	0	Halting debug mode enable
		ERR	0	Cumulative error flag
EDECCR	Cold	NSE[2:1]	0b00	Coarse-grained Non-secure exception catch
		SE[3,1]	0b00	Coarse-grained Secure exception catch
EDPCSR	Cold	-	-	All fields
EDCIDSR	Cold	-	-	All fields
EDVIDSR	Cold	-	-	All fields
EDPRCR	External debug	COREPURQ[a]	0	Core powerup request
EDPRSR	Warm	SDR	-	Sticky debug restart
	Cold	SPMAD	0	Sticky EPMAD error
		SDAD	0	Sticky EDAD error
	Warm	SR	1	Sticky reset status
	Cold	SPD	1	Sticky powerdown status

a. On a cold reset into AArch64 state, DBGPRCR_EL1.CORENPRDRQ resets to the value of EDPRCR.COREPURQ. On a cold reset into AArch32 state, DBGPRCR.CORENPRDRQ resets to the value of EDPRCR.COREPURQ.If an External Debug reset and a Cold reset coincide, both EDPRCR.COREPURQ and the CORENPRDRQ field of the appropriate System register are reset to 0.

Table H8-7 shows the reset values for the CTI registers

Table H8-7 Summary of external debug register resets, CTI registers

Register	Reset domain	Field	Value	Description
CTICONTROL	External debug	GLBEN	0	CTI global enable
CTIAPPSET	External debug	-	-	All fields
CTIINEN<n>	External debug	-	-	All fields
CTIOUTEN<n>	External debug	-	-	All fields
CTIGATE	External debug	-	-	All fields

Chapter H9
External Debug Register Descriptions

This chapter provides a description of the external debug registers.

It contains the following sections:

- *Introduction* on page H9-4832.
- *Debug registers* on page H9-4833.
- *Cross-Trigger Interface registers* on page H9-4919.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.1 Introduction

This section lists the registers that are accessible through the external debug interface.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2 Debug registers

This section lists the Debug registers.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.1 DBGAUTHSTATUS_EL1, Debug Authentication Status register

The DBGAUTHSTATUS_EL1 characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

External register DBGAUTHSTATUS_EL1 is architecturally mapped to AArch64 System register DBGAUTHSTATUS_EL1.

External register DBGAUTHSTATUS_EL1 is architecturally mapped to AArch32 System register DBGAUTHSTATUS.

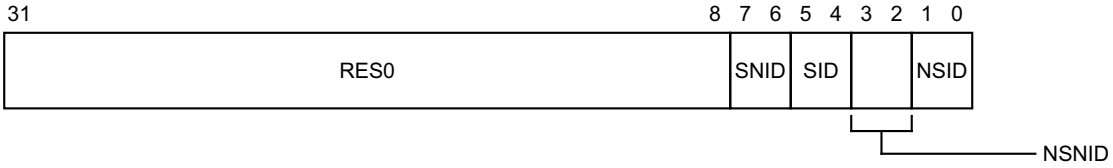
DBGAUTHSTATUS_EL1 is in the Debug power domain.

Attributes

DBGAUTHSTATUS_EL1 is a 32-bit register.

Field descriptions

The DBGAUTHSTATUS_EL1 bit assignments are:



Bits [31:8]

Reserved, RES0.

SNID, bits [7:6]

Secure non-invasive debug. Possible values of this field are:

`00` Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state.

`10` Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.

`11` Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.

SID, bits [5:4]

Secure invasive debug. Possible values of this field are:

`00` Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state.

`10` Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.

`11` Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Other values are reserved.

NSNID, bits [3:2]

Non-secure non-invasive debug. Possible values of this field are:

00 Not implemented. EL3 is not implemented and the implemented Security state is Secure state.

10 Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.

11 Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.

NSID, bits [1:0]

Non-secure invasive debug. Possible values of this field are:

00 Not implemented. EL3 is not implemented and the implemented Security state is Secure state.

10 Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.

11 Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

Other values are reserved.

Accessing the DBGAUTHSTATUS_EL1:

DBGAUTHSTATUS_EL1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFB8

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.2 DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 15

The DBGBCR<n>_EL1 characteristics are:

Purpose

Holds control information for a breakpoint. Forms breakpoint n together with value register DBGBVR<n>_EL1.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EDAD	SLK	Default
Error	Error	Error	Error	RO	RW

When the E field is zero, all the other fields in the register are ignored.

Configurations

External register DBGBCR<n>_EL1 is architecturally mapped to AArch64 System register DBGBCR<n>_EL1.

External register DBGBCR<n>_EL1 is architecturally mapped to AArch32 System register DBGBCR<n>.

DBGBCR<n>_EL1 is in the Core power domain.

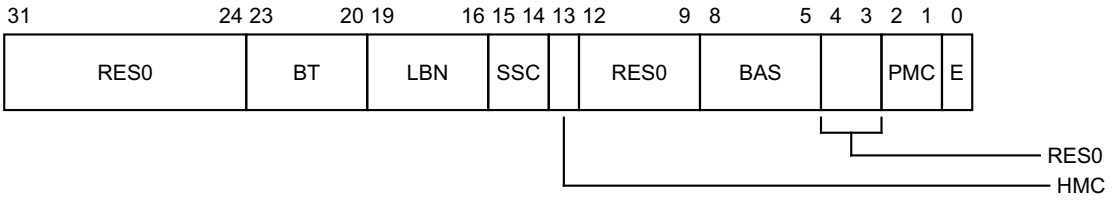
If breakpoint n is not implemented then this register is unallocated.

Attributes

DBGBCR<n>_EL1 is a 32-bit register.

Field descriptions

The DBGBCR<n>_EL1 bit assignments are:



Bits [31:24]

Reserved, RES0.

BT, bits [23:20]

Breakpoint Type. Possible values are:

`0000` Unlinked instruction address match.

`0001` Linked instruction address match.

`0010` Unlinked context ID match.

`0011` Linked context ID match

`0100` Unlinked instruction address mismatch.

`0101` Linked instruction address mismatch.

`1000` Unlinked VMID match.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

1001 Linked VMID match.

1010 Unlinked VMID and context ID match.

1011 Linked VMID and context ID match.

The field breaks down as follows:

- BT[3:1]: Base type.

  000 Match address. DBGBVR<n>_EL1 is the address of an instruction.

  010 Mismatch address. DBGBVR<n>_EL1 is the address of an instruction to be stepped.

  001 Match context ID. DBGBVR<n>_EL1.ContextID is a context ID.

  100 Match VMID. DBGBVR<n>_EL1.VMID is a VMID.

  101 Match VMID and context ID. DBGBVR<n>_EL1.ContextID is a context ID, and DBGBVR<n>_EL1.VMID is a VMID.

- BT[0]: Enable linking.

All other values are reserved. Constraints on breakpoint programming mean other values are reserved under some conditions. For more information, including the effect of programming this field to a reserved value, see *Reserved DBGBCR<n>_EL1.BT values* on page D2-1579.

LBN, bits [19:16]

Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.

For all other breakpoint types this field is ignored and reads of the register return an UNKNOWN value.

This field is ignored when the value of DBGBCR<n>_EL1.E is 0.

SSC, bits [15:14]

Security state control. Determines the Security states under which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the HMC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information, including the effect of programming the fields to a reserved set of values, see *Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values* on page D2-1580.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see DBGBCR<n>_EL1.SSC description.

Bits [12:9]

Reserved, RES0.

BAS, bits [8:5]

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and Execution state. In an AArch64-only implementation, this field is reserved, RES1. Otherwise:

- BAS[2] and BAS[0] are read/write.
- BAS[3] and BAS[1] are read-only copies of BAS[2] and BAS[0] respectively.

The values 0011 and 1100 are only supported if AArch32 is supported at any Exception level.

The permitted values depend on the breakpoint type.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

For Address match breakpoints in either AArch32 or AArch64 state, the permitted values are:

BAS	Match instruction at	Constraint for debuggers
0011	DBGBVR<n>_EL1	Use for T32 instructions.
1100	DBGBVR<n>_EL1+2	Use for T32 instructions.
1111	DBGBVR<n>_EL1	Use for A64 and A32 instructions.

0000 is reserved and must behave as if the breakpoint is disabled or map to a permitted value.

For more information, see *Using the BAS field in Address Match breakpoints* on page G2-3805.

For Address mismatch breakpoints in an AArch32 stage 1 translation regime, the permitted values are:

BAS	Step instruction at	Constraint for debuggers
0000	-	Use for a match anywhere breakpoint.
0011	DBGBVR<n>_EL1	Use for stepping T32 instructions.
1100	DBGBVR<n>_EL1+2	Use for stepping T32 instructions.
1111	DBGBVR<n>_EL1	Use for stepping A64 and A32 instructions.

For more information, see *Using the BAS field in Address Match breakpoints* on page G2-3805.

For Context matching breakpoints, this field is RES1 and ignored.

Bits [4:3]

Reserved, RES0.

PMC, bits [2:1]

Privilege mode control. Determines the Exception level or levels at which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see the DBGBCR<n>_EL1.SSC description.

E, bit [0]

Enable breakpoint DBGBVR<n>_EL1. Possible values are:

0 Breakpoint disabled.

1 Breakpoint enabled.

Accessing the DBGBCR<n>_EL1:

DBGBCR<n>_EL1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x408 + 16n

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.3 DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 15

The DBGBVR<n>_EL1 characteristics are:

Purpose

Holds a virtual address, or a VMID and/or a context ID, for use in breakpoint matching. Forms breakpoint n together with control register DBGBCR<n>_EL1.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EDAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register DBGBVR<n>_EL1 is architecturally mapped to AArch64 System register DBGBVR<n>_EL1.

External register DBGBVR<n>_EL1[31:0] is architecturally mapped to AArch32 System register DBGBVR<n>.

External register DBGBVR<n>_EL1[63:32] is architecturally mapped to AArch32 System register DBGBXVR<n>.

DBGBVR<n>_EL1 is in the Core power domain.

If breakpoint n is not implemented then this register is unallocated.

Attributes

How this register is interpreted depends on the value of DBGBCR<n>_EL1.BT.

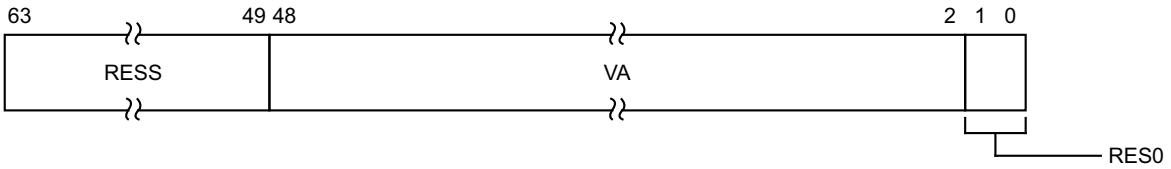
- When DBGBCR<n>_EL1.BT is 0b0x0x, this register holds a virtual address.
- When DBGBCR<n>_EL1.BT is 0b001x, this register holds a Context ID.
- When DBGBCR<n>_EL1.BT is 0b100x, this register holds a VMID.
- When DBGBCR<n>_EL1.BT is 0b101x, this register holds a VMID and a Context ID.

For other values of DBGBCR<n>_EL1.BT, this register is RES0.

Field descriptions

The DBGBVR<n>_EL1 bit assignments are:

When DBGBCR<n>_EL1.BT==0b0x0x:



RESS, bits [63:49]

Reserved, Sign extended. Software must treat this field as RES0 if bit[48] is 0 or RES0, and as RES1 if bit[48] is 1.

Hardware always ignores the value of these bits and it is IMPLEMENTATION DEFINED whether:

- The bits are hardwired to a copy of bit [48], meaning writes to these bits are ignored, and reads to the bits always return the hardwired value.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- The value in those bits can be written, and reads will return the last value written. The value held in those bits is ignored by hardware.

VA, bits [48:2]

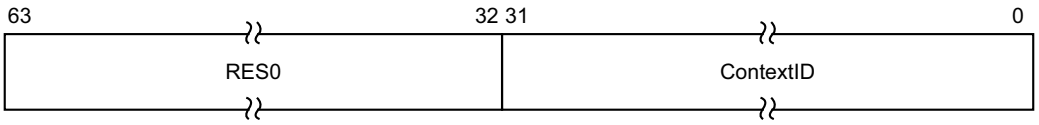
If the address is being matched in an AArch64 stage 1 translation regime, this field contains bits[48:2] of the address for comparison.

If the address is being matched in an AArch32 stage 1 translation regime, the first 16 bits of this field are RES0, and the rest of the field contains bits[31:2] of the address for comparison.

Bits [1:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT==0b001x:



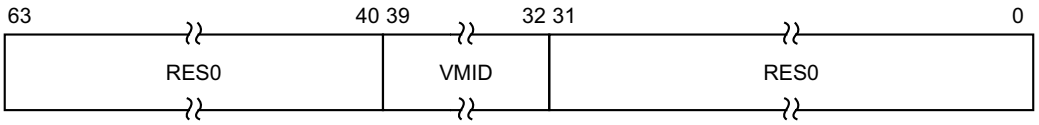
Bits [63:32]

Reserved, RES0.

ContextID, bits [31:0]

Context ID value for comparison.

When DBGBCR<n>_EL1.BT==0b100x and EL2 implemented:



Bits [63:40]

Reserved, RES0.

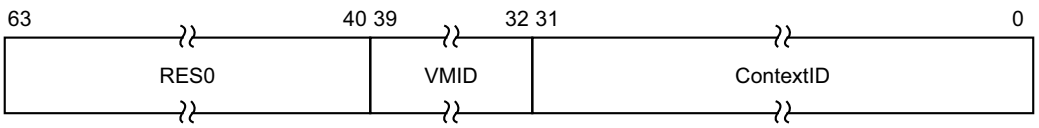
VMID, bits [39:32]

VMID value for comparison.

Bits [31:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT==0b101x and EL2 implemented:



Bits [63:40]

Reserved, RES0.

VMID, bits [39:32]

VMID value for comparison.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

ContextID, bits [31:0]

Context ID value for comparison.

Accessing the DBGBVR<n>_EL1:

DBGBVR<n>_EL1[31:0] can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x400 + 16n

DBGBVR<n>_EL1[63:32] can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x404 + 16n

Non-Confidential - Beta

H9.2.4 DBGCLAIMCLR_EL1, Debug Claim Tag Clear register

The DBGCLAIMCLR_EL1 characteristics are:

Purpose

Used by software to read the values of the CLAIM tag bits, and to clear these bits to 0.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

The architecture does not define any functionality for the CLAIM tag bits.

Note

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the DBGCLAIMSET_EL1 register.

Configurations

External register DBGCLAIMCLR_EL1 is architecturally mapped to AArch64 System register DBGCLAIMCLR_EL1.

External register DBGCLAIMCLR_EL1 is architecturally mapped to AArch32 System register DBGCLAIMCLR.

DBGCLAIMCLR_EL1 is in the Core power domain.

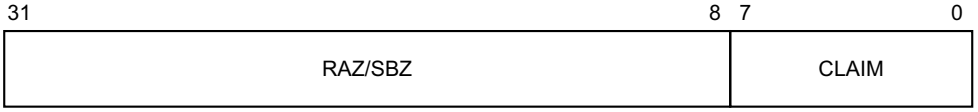
An implementation must include 8 CLAIM tag bits.

Attributes

DBGCLAIMCLR_EL1 is a 32-bit register.

Field descriptions

The DBGCLAIMCLR_EL1 bit assignments are:



Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Read or clear CLAIM tag bits. Reading this field returns the current value of the CLAIM tag bits.

Writing a 1 to one of these bits clears the corresponding CLAIM tag bit to 0. This is an indirect write to the CLAIM tag bits. A single write operation can clear multiple CLAIM tag bits to 0.

Writing 0 to one of these bits has no effect.

A Cold reset clears the CLAIM tag bits to 0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the DBGCLAIMCLR_EL1:

DBGCLAIMCLR_EL1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFA4

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.5 DBGCLAIMSET_EL1, Debug Claim Tag Set register

The DBGCLAIMSET_EL1 characteristics are:

Purpose

Used by software to set the CLAIM tag bits to 1.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

The architecture does not define any functionality for the CLAIM tag bits.

Note

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the DBGCLAIMCLR_EL1 register.

Configurations

External register DBGCLAIMSET_EL1 is architecturally mapped to AArch64 System register DBGCLAIMSET_EL1.

External register DBGCLAIMSET_EL1 is architecturally mapped to AArch32 System register DBGCLAIMSET.

DBGCLAIMSET_EL1 is in the Core power domain.

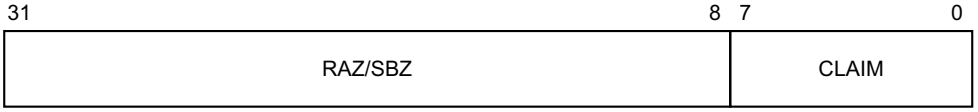
An implementation must include 8 CLAIM tag bits.

Attributes

DBGCLAIMSET_EL1 is a 32-bit register.

Field descriptions

The DBGCLAIMSET_EL1 bit assignments are:



Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Set CLAIM tag bits. RAO.

Writing a 1 to one of these bits sets the corresponding CLAIM tag bit to 1. This is an indirect write to the CLAIM tag bits. A single write operation can set multiple CLAIM tag bits to 1.

Writing 0 to one of these bits has no effect.

A Cold reset clears the CLAIM tag bits to 0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the DBGCLAIMSET_EL1:

DBGCLAIMSET_EL1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFA0

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.6 DBGDTRRX_EL0, Debug Data Transfer Register, Receive

The DBGDTRRX_EL0 characteristics are:

Purpose

Transfers data from an external debugger to the PE. For example, it is used by a debugger transferring commands and data to a debug target. It is a component of the Debug Communications Channel.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

If EDSCR.ITE == 0 when the PE exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state before the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

Configurations

External register DBGDTRRX_EL0 is architecturally mapped to AArch64 System register DBGDTRRX_EL0.

External register DBGDTRRX_EL0 is architecturally mapped to AArch32 System register DBGDTRRXint.

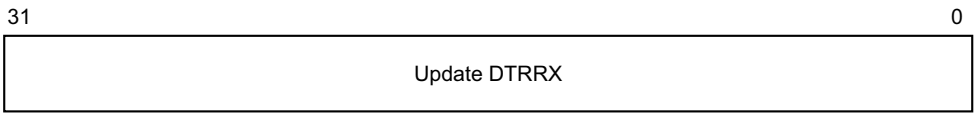
DBGDTRRX_EL0 is in the Core power domain.

Attributes

DBGDTRRX_EL0 is a 32-bit register.

Field descriptions

The DBGDTRRX_EL0 bit assignments are:



Bits [31:0]

Update DTRRX.

If RXfull is set to 0, then writes to this register update the value in DTRRX and set RXfull to 1.

Reads of this register return the last value written to DTRRX and do not change RXfull.

For the full behavior of the Debug Communications Channel, see Chapter H4 *The Debug Communication Channel and Instruction Transfer Register*.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the DBGDTRRX_EL0:

DBGDTRRX_EL0 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x080

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.7 DBGDTRTX_EL0, Debug Data Transfer Register, Transmit

The DBGDTRTX_EL0 characteristics are:

Purpose

Transfers data from the PE to an external debugger. For example, it is used by a debug target to transfer data to the debugger. It is a component of the Debug Communication Channel.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

If EDSCR.ITE == 0 when the PE exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state before the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

Configurations

External register DBGDTRTX_EL0 is architecturally mapped to AArch64 System register DBGDTRTX_EL0.

External register DBGDTRTX_EL0 is architecturally mapped to AArch32 System register DBGDTRTXint.

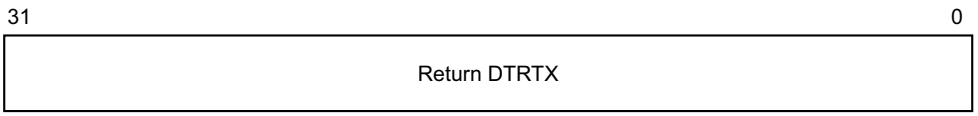
DBGDTRTX_EL0 is in the Core power domain.

Attributes

DBGDTRTX_EL0 is a 32-bit register.

Field descriptions

The DBGDTRTX_EL0 bit assignments are:



Bits [31:0]

Return DTRTX.

If TXfull is set to 1, then reads of this register return the value in DTRTX and clear TXfull to 0.

Writes of this register update the value in DTRTX and do not change TXfull.

For the full behavior of the Debug Communications Channel, see Chapter H4 *The Debug Communication Channel and Instruction Transfer Register*.

Non-Confidential - Beta

Accessing the DBGDTRTX_EL0:

DBGDTRTX_EL0 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x08C

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.8 DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<n>_EL1 characteristics are:

Purpose

Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<n>_EL1.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EDAD	SLK	Default
Error	Error	Error	Error	RO	RW

When the E field is zero, all the other fields in the register are ignored.

Configurations

External register DBGWCR<n>_EL1 is architecturally mapped to AArch64 System register DBGWCR<n>_EL1.

External register DBGWCR<n>_EL1 is architecturally mapped to AArch32 System register DBGWCR<n>.

DBGWCR<n>_EL1 is in the Core power domain.

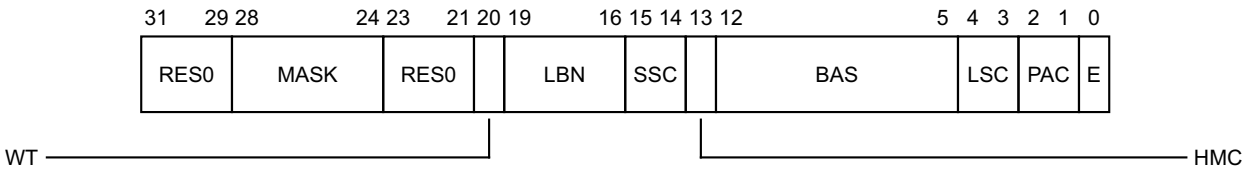
If breakpoint n is not implemented then this register is unallocated.

Attributes

DBGWCR<n>_EL1 is a 32-bit register.

Field descriptions

The DBGWCR<n>_EL1 bit assignments are:



Bits [31:29]

Reserved, RES0.

MASK, bits [28:24]

Address mask. Only objects up to 2GB can be watched using a single mask.

`00000` No mask.

`00001` Reserved.

`00010` Reserved.

If programmed with a reserved value, a watchpoint must behave as if either:

- MASK has been programmed with a defined value, which might be 0 (no mask), other than for a direct read of DBGWCRn_EL1.
- The watchpoint is disabled.

Software must not rely on this property because the behavior of reserved values might change in a future revision of the architecture.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Other values mask the corresponding number of address bits, from 0b00011 masking 3 address bits (0x00000007 mask for address) to 0b11111 masking 31 address bits (0x7FFFFFFF mask for address).

Bits [23:21]

Reserved, RES0.

WT, bit [20]

Watchpoint type. Possible values are:

0 Unlinked data address match.

1 Linked data address match.

LBN, bits [19:16]

Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.

SSC, bits [15:14]

Security state control. Determines the Security states under which a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.

BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by DBGWVR<n>_EL1 is being watched.

BAS	Description
xxxxxxx1	Match byte at DBGWVR<n>_EL1
xxxxxx1x	Match byte at DBGWVR<n>_EL1+1
xxxxx1xx	Match byte at DBGWVR<n>_EL1+2
xxxx1xxx	Match byte at DBGWVR<n>_EL1+3

In cases where DBGWVR<n>_EL1 addresses a double-word:

BAS	Description, if DBGWVR<n>_EL1[2] == 0
xxx1xxxx	Match byte at DBGWVR<n>_EL1+4
xx1xxxxx	Match byte at DBGWVR<n>_EL1+5
x1xxxxxx	Match byte at DBGWVR<n>_EL1+6
1xxxxxxx	Match byte at DBGWVR<n>_EL1+7

If DBGWVR<n>_EL1[2] == 1, only BAS[3:0] is used. ARM deprecates setting DBGWVR<n>_EL1[2] == 1.

The valid values for BAS are 0b00000000, or a binary number all of whose set bits are contiguous. All other values are reserved and must not be used by software.

If BAS is zero, no bytes are watched by this watchpoint.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

`01` Match instructions that load from a watchpointed address.

`10` Match instructions that store to a watchpointed address.

`11` Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

PAC, bits [2:1]

Privilege of access control. Determines the Exception level or levels at which a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

E, bit [0]

Enable watchpoint n. Possible values are:

`0` Watchpoint disabled.

`1` Watchpoint enabled.

Accessing the DBGWCR<n>_EL1:

DBGWCR<n>_EL1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0x808` + 16n

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.9 DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 15

The DBGWVR<n>_EL1 characteristics are:

Purpose

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register DBGWCR<n>_EL1.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EDAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register DBGWVR<n>_EL1 is architecturally mapped to AArch64 System register DBGWVR<n>_EL1.

External register DBGWVR<n>_EL1[31:0] is architecturally mapped to AArch32 System register DBGWVR<n>.

DBGWVR<n>_EL1 is in the Core power domain.

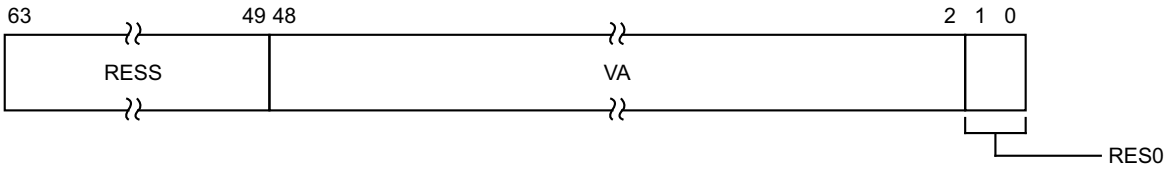
If breakpoint n is not implemented then this register is unallocated.

Attributes

DBGWVR<n>_EL1 is a 64-bit register.

Field descriptions

The DBGWVR<n>_EL1 bit assignments are:



RESS, bits [63:49]

Reserved, Sign extended. Hardware and software must treat this field as RES0 if bit[48] is 0 or RES0, and as RES1 if bit[48] is 1.

Hardware always ignores the value of these bits and it is IMPLEMENTATION DEFINED whether:

- The bits are hardwired to a copy of bit [48], meaning writes to these bits are ignored, and reads to the bits always return the hardwired value.
- The value in those bits can be written, and reads will return the last value written. The value held in those bits is ignored by hardware.

VA, bits [48:2]

Bits[48:2] of the address value for comparison.

ARM deprecates setting DBGWVR<n>_EL1[2] == 1.

Bits [1:0]

Reserved, RES0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the DBGWVR<n>_EL1:

DBGWVR<n>_EL1[31:0] can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x800 + 16n

DBGWVR<n>_EL1[63:32] can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x804 + 16n

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.10 EDAA32PFR, External Debug AArch32 Processor Feature Register

The EDAA32PFR characteristics are:

Purpose

Provides additional information about implemented PE features in AArch32.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

EDAA32PFR is in the Debug power domain.

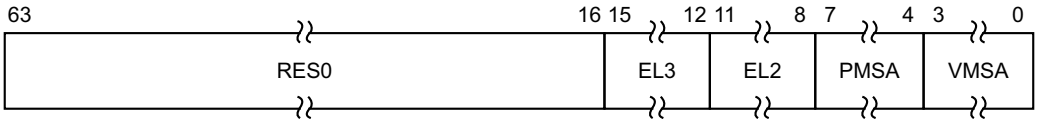
EDAA32PFR is only accessible in an AArch32-only implementation. If AArch64 is supported at any Exception level, EDAA32PFR is RES0.

Attributes

EDAA32PFR is a 64-bit register.

Field descriptions

The EDAA32PFR bit assignments are:



Bits [63:16]

Reserved, RES0.

EL3, bits [15:12]

AArch32 EL3 Exception level handling. Defined values are:

`0000` EL3 is not implemented.

`0001` EL3 can be executed in AArch32 state only.

When the value of EDPFR.EL3 is non-zero, this field must be `0000`.

All other values are reserved.

Note

EDPFR.{EL1, EL0} indicate whether EL1 and EL0 can only be executed in AArch32 state.

EL2, bits [11:8]

AArch32 EL2 Exception level handling. Defined values are:

`0000` EL2 is not implemented.

`0001` EL2 can be executed in AArch32 state only.

When the value of EDPFR.EL2 is non-zero, this field must be `0000`.

All other values are reserved.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Note

EDPFR.{EL1, EL0} indicate whether EL1 and EL0 can only be executed in AArch32 state.

PMSA, bits [7:4]

Indicates support for an ARMv8-R PMSA. Defined values are:

`0000` PMSA not supported.

`0100` Support for an ARMv8-R PMSAv8.

All other values are reserved. In ARMv8-A, the only permitted value is `0000`.

VMSA, bits [3:0]

Indicates support for an ARMv8-R VMSA. Defined values are:

`0000` VMSA not supported.

`0101` Support for an ARMv8-R VMSAv8-32.

All other values are reserved. In ARMv8-A, the only permitted value is `0000`.

Accessing the EDAA32PFR:

EDAA32PFR can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xD60`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.11 EDACR, External Debug Auxiliary Control Register

The EDACR characteristics are:

Purpose

Allows implementations to support IMPLEMENTATION DEFINED controls.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
IMP DEF	IMP DEF	IMP DEF	RO	RW

Configurations

It is IMPLEMENTATION DEFINED whether EDACR is in the Core power domain or in the Debug power domain.

Attributes

EDACR is a 32-bit register.

Field descriptions

The EDACR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the EDACR:

EDACR can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x094

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.12 EDCIDR0, External Debug Component Identification Register 0

The EDCIDR0 characteristics are:

Purpose

Provides information to identify an external debug component.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

EDCIDR0 is in the Debug power domain.

EDCIDR0 is optional to implement in the external register interface.

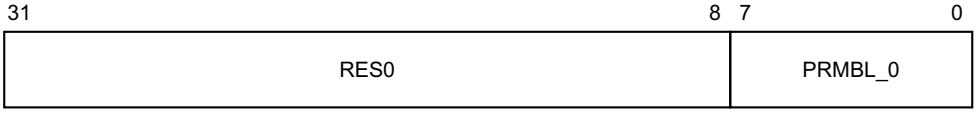
This register is required for CoreSight compliance.

Attributes

EDCIDR0 is a 32-bit register.

Field descriptions

The EDCIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_0, bits [7:0]

Preamble. Must read as `0x0D`.

Accessing the EDCIDR0:

EDCIDR0 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFF0`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.13 EDCIDR1, External Debug Component Identification Register 1

The EDCIDR1 characteristics are:

Purpose

Provides information to identify an external debug component.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

EDCIDR1 is in the Debug power domain.

EDCIDR1 is optional to implement in the external register interface.

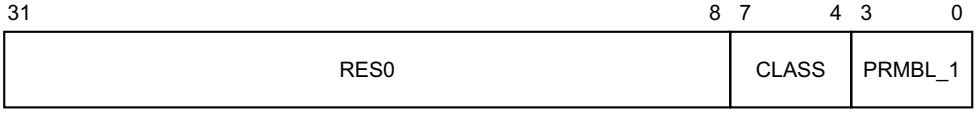
This register is required for CoreSight compliance.

Attributes

EDCIDR1 is a 32-bit register.

Field descriptions

The EDCIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

CLASS, bits [7:4]

Component class. Reads as `0x9`, debug component.

PRMBL_1, bits [3:0]

Preamble. RAZ.

Accessing the EDCIDR1:

EDCIDR1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFF4`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.14 EDCIDR2, External Debug Component Identification Register 2

The EDCIDR2 characteristics are:

Purpose

Provides information to identify an external debug component.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

EDCIDR2 is in the Debug power domain.

EDCIDR2 is optional to implement in the external register interface.

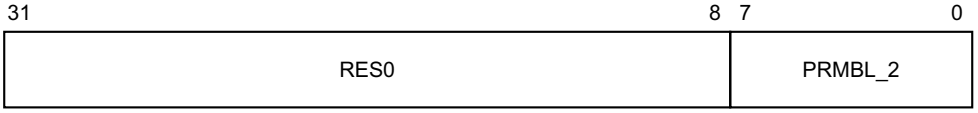
This register is required for CoreSight compliance.

Attributes

EDCIDR2 is a 32-bit register.

Field descriptions

The EDCIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

Preamble. Must read as `0x05`.

Accessing the EDCIDR2:

EDCIDR2 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFF8`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.15 EDCIDR3, External Debug Component Identification Register 3

The EDCIDR3 characteristics are:

Purpose

Provides information to identify an external debug component.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

EDCIDR3 is in the Debug power domain.

EDCIDR3 is optional to implement in the external register interface.

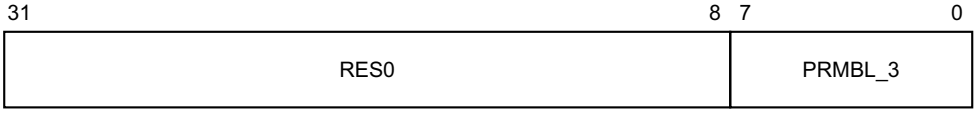
This register is required for CoreSight compliance.

Attributes

EDCIDR3 is a 32-bit register.

Field descriptions

The EDCIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_3, bits [7:0]

Preamble. Must read as `0xB1`.

Accessing the EDCIDR3:

EDCIDR3 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFFC`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.16 EDCIDSR, External Debug Context ID Sample Register

The EDCIDSR characteristics are:

Purpose

Contains the sampled value of CONTEXTIDR_EL1, captured on reading the low half of EDPCSR.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	Default
Error	Error	Error	RO

Configurations

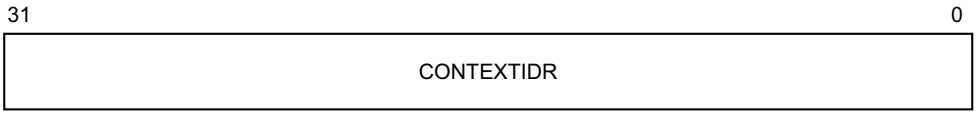
EDCIDSR is in the Core power domain.

Attributes

EDCIDSR is a 32-bit register.

Field descriptions

The EDCIDSR bit assignments are:



CONTEXTIDR, bits [31:0]

The sampled value of CONTEXTIDR_EL1, captured on reading the low half of EDPCSR.

If EL3 is implemented and using AArch32 then CONTEXTIDR is a Banked register, and EDCIDSR samples the current Banked copy of CONTEXTIDR.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the EDCIDSR:

EDCIDSR can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x0A4

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.17 EDDEVAFF0, External Debug Device Affinity register 0

The EDDEVAFF0 characteristics are:

Purpose

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the external debug component relates to.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

EDDEVAFF0 is in the Debug power domain.

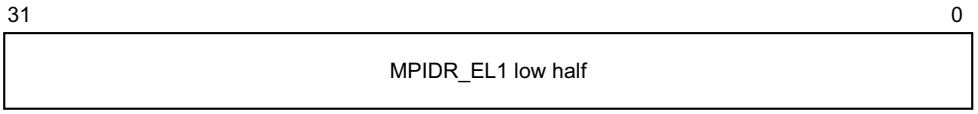
EDDEVAFF0 is optional to implement in the external register interface.

Attributes

EDDEVAFF0 is a 32-bit register.

Field descriptions

The EDDEVAFF0 bit assignments are:



Bits [31:0]

MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented Exception level.

Accessing the EDDEVAFF0:

EDDEVAFF0 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFA8

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.18 EDDEVAFF1, External Debug Device Affinity register 1

The EDDEVAFF1 characteristics are:

Purpose

Copy of the high half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the external debug component relates to.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

EDDEVAFF1 is in the Debug power domain.

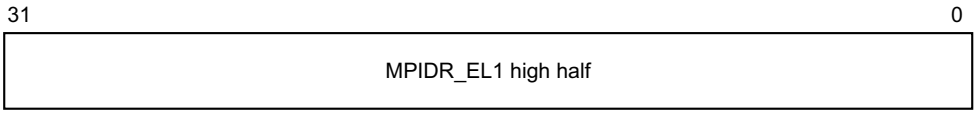
EDDEVAFF1 is optional to implement in the external register interface.

Attributes

EDDEVAFF1 is a 32-bit register.

Field descriptions

The EDDEVAFF1 bit assignments are:



Bits [31:0]

MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented Exception level.

Accessing the EDDEVAFF1:

EDDEVAFF1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFAC

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.19 EDDEVARCH, External Debug Device Architecture register

The EDDEVARCH characteristics are:

Purpose

Identifies the programmers' model architecture of the external debug component.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

EDDEVARCH is in the Debug power domain.

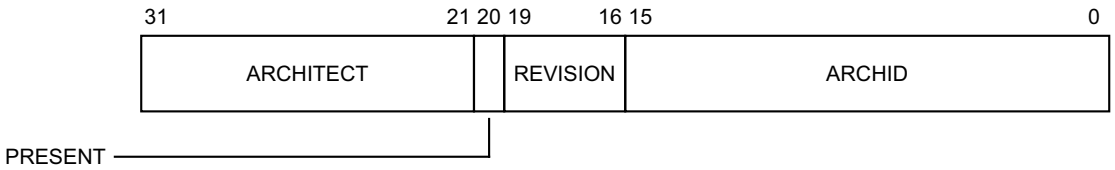
EDDEVARCH is optional to implement in the external register interface.

Attributes

EDDEVARCH is a 32-bit register.

Field descriptions

The EDDEVARCH bit assignments are:



ARCHITECT, bits [31:21]

Defines the architecture of the component. For debug, this is ARM Limited.

Bits [31:28] are the JEP 106 continuation code, `0x4`.

Bits [27:21] are the JEP 106 ID code, `0x3B`.

PRESENT, bit [20]

When set to 1, indicates that the DEVARCH is present.

This field is 1 in ARMv8.

REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by ARM this is the minor revision.

For debug, the revision defined by ARMv8 is `0x0`.

All other values are reserved.

ARCHID, bits [15:0]

Defines this part to be an ARMv8 debug component. For architectures defined by ARM this is further subdivided.

For debug:

- Bits [15:12] are the architecture version, `0x6`.
- Bits [11:0] are the architecture part number, `0xA15`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

This corresponds to the ARMv8 debug architecture version.

Accessing the EDDEVARCH:

EDDEVARCH can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFBC

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.20 EDDEVID, External Debug Device ID register 0

The EDDEVID characteristics are:

Purpose

Provides extra information for external debuggers about features of the debug implementation.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

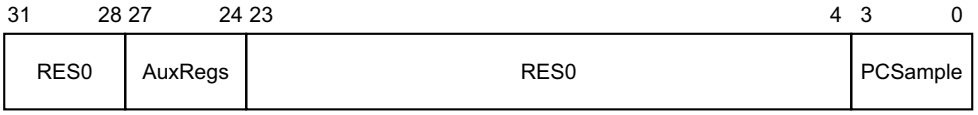
EDDEVID is in the Debug power domain.

Attributes

EDDEVID is a 32-bit register.

Field descriptions

The EDDEVID bit assignments are:



Bits [31:28]

Reserved, RES0.

AuxRegs, bits [27:24]

Indicates support for Auxiliary registers. Permitted values for this field are:

`0000` None supported.

`0001` Support for External Debug Auxiliary Control Register, EDACR.

All other values are reserved.

Bits [23:4]

Reserved, RES0.

PCSample, bits [3:0]

Indicates the level of Sample-based profiling support using external debug registers 40 through 43. Permitted values of this field in ARMv8 are:

`0000` Architecture-defined form of Sample-based profiling not implemented.

`0010` EDPCSR and EDCIDSR are implemented (only permitted if EL3 and EL2 are not implemented).

`0011` EDPCSR, EDCIDSR, and EDVIDSR are implemented.

All other values are reserved.

Non-Confidential - Beta

Accessing the EDDEVID:

EDDEVID can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFC8

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.21 EDDEVID1, External Debug Device ID register 1

The EDDEVID1 characteristics are:

Purpose

Provides extra information for external debuggers about features of the debug implementation.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

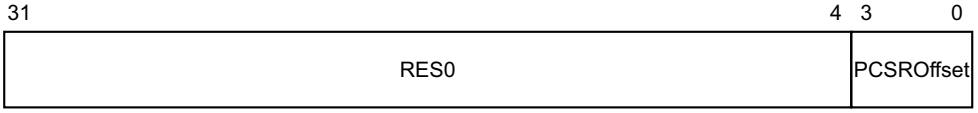
EDDEVID1 is in the Debug power domain.

Attributes

EDDEVID1 is a 32-bit register.

Field descriptions

The EDDEVID1 bit assignments are:



Bits [31:4]

Reserved, RES0.

PCSROffset, bits [3:0]

This field indicates the offset applied to PC samples returned by reads of EDPCSR. Permitted values of this field in ARMv8 are:

`0000` EDPCSR not implemented.

`0010` EDPCSR implemented, and samples have no offset applied and do not sample the instruction set state in AArch32 state.

Accessing the EDDEVID1:

EDDEVID1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFC4`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.22 EDDEVID2, External Debug Device ID register 2

The EDDEVID2 characteristics are:

Purpose

Reserved for future descriptions of features of the debug implementation.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

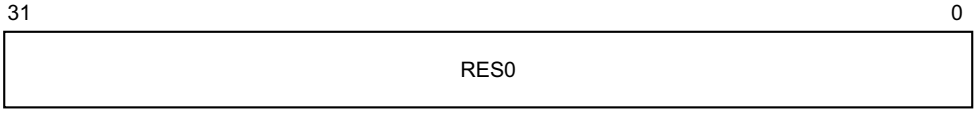
EDDEVID2 is in the Debug power domain.

Attributes

EDDEVID2 is a 32-bit register.

Field descriptions

The EDDEVID2 bit assignments are:



Bits [31:0]

Reserved, RES0.

Accessing the EDDEVID2:

EDDEVID2 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFC0

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.23 EDDEVTYPE, External Debug Device Type register

The EDDEVTYPE characteristics are:

Purpose

Indicates to a debugger that this component is part of a PEs debug logic.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

EDDEVTYPE is in the Debug power domain.

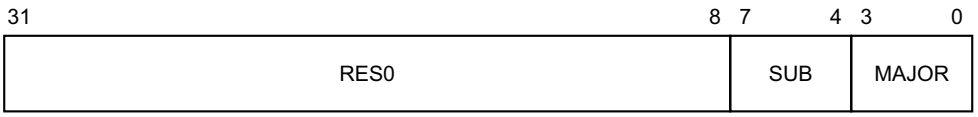
EDDEVTYPE is optional to implement in the external register interface.

Attributes

EDDEVTYPE is a 32-bit register.

Field descriptions

The EDDEVTYPE bit assignments are:



Bits [31:8]

Reserved, RES0.

SUB, bits [7:4]

Subtype. Must read as `0x1` to indicate this is a component within a PE.

MAJOR, bits [3:0]

Major type. Must read as `0x5` to indicate this is a debug logic component.

Accessing the EDDEVTYPE:

EDDEVTYPE can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFCC`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.24 EDDFR, External Debug Feature Register

The EDDFR characteristics are:

Purpose

Provides top level information about the debug system in AArch64.

Usage constraints

This register is accessible as follows:

Default
RO

Debuggers must use EDDEVARCH to determine the Debug architecture version.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page D7-1806.

Configurations

External register EDDFR is architecturally mapped to AArch64 System register ID_AA64DFR0_EL1.

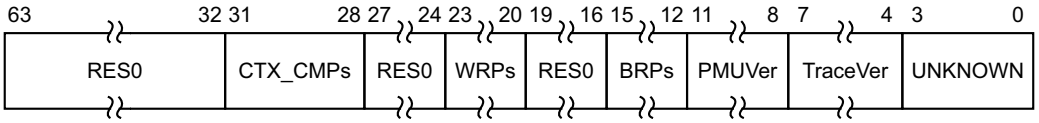
EDDFR is in the Debug power domain.

Attributes

EDDFR is a 64-bit register.

Field descriptions

The EDDFR bit assignments are:



Bits [63:32]

Reserved, RES0.

CTX_CMPs, bits [31:28]

Number of breakpoints that are context-aware, minus 1. These are the highest numbered breakpoints.

Bits [27:24]

Reserved, RES0.

WRPs, bits [23:20]

Number of watchpoints, minus 1. The value of `0b0000` is reserved.

Bits [19:16]

Reserved, RES0.

BRPs, bits [15:12]

Number of breakpoints, minus 1. The value of `0b0000` is reserved.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

PMUVer, bits [11:8]

Performance Monitors extension version. Indicates whether System register interface to Performance Monitors extension is implemented. Defined values are:

`0000` Performance Monitors extension System registers not implemented.

`0001` Performance Monitors extension System registers implemented, PMUv3.

`1111` IMPLEMENTATION DEFINED form of performance monitors supported, PMUv3 not supported.

All other values are reserved.

TraceVer, bits [7:4]

Trace support. Indicates whether System register interface to a trace macrocell is implemented. Defined values are:

`0000` Trace macrocell System registers not implemented.

`0001` Trace macrocell System registers implemented.

All other values are reserved.

A value of `0000` only indicates that no System register interface to a trace macrocell is implemented. A trace macrocell might nevertheless be implemented without a System register interface.

UNKNOWN, bits [3:0]

Reserved, UNKNOWN.

Accessing the EDDFR:

EDDFR[31:0] can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xD28`

EDDFR[63:32] can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xD2C`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.25 EDECCR, External Debug Exception Catch Control Register

The EDECCR characteristics are:

Purpose

Controls exception catch debug events.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

Configurations

External register EDECCR is architecturally mapped to AArch64 System register OSECCR_EL1.

External register EDECCR is architecturally mapped to AArch32 System register DBGOSECCR.

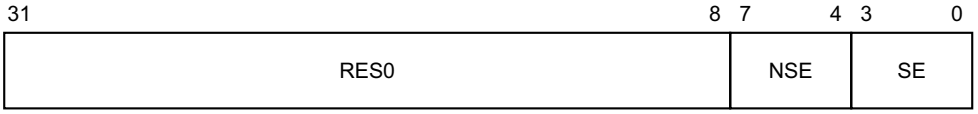
EDECCR is in the Core power domain.

Attributes

EDECCR is a 32-bit register.

Field descriptions

The EDECCR bit assignments are:



Bits [31:8]

Reserved, RES0.

NSE, bits [7:4]

Coarse-grained Non-secure exception catch. Possible values of this field are:

`0000` Exception catch debug event disabled for Non-secure Exception levels.

`0010` Exception catch debug event enabled for Non-secure EL1.

`0100` Exception catch debug event enabled for Non-secure EL2.

`0110` Exception catch debug event enabled for Non-secure EL1 and EL2.

All other values are reserved. Bits [7,4] are reserved, RES0.

When this register has an architecturally-defined reset value, this field resets to `0`.

SE, bits [3:0]

Coarse-grained Secure exception catch. Possible values of this field are:

`0000` Exception catch debug event disabled for Secure Exception levels.

`0010` Exception catch debug event enabled for Secure EL1.

`1000` Exception catch debug event enabled for Secure EL3.

`1010` Exception catch debug event enabled for Secure EL1 and EL3.

All other values are reserved. Bits [2,0] are reserved. RES0. Ignored if ExternalSecureInvasiveDebugEnabled() == FALSE.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

When this register has an architecturally-defined reset value, this field resets to `0`.

Accessing the EDECCR:

EDECCR can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0x098`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.26 EDECR, External Debug Execution Control Register

The EDECR characteristics are:

Purpose

Controls Halting debug events.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RW

Configurations

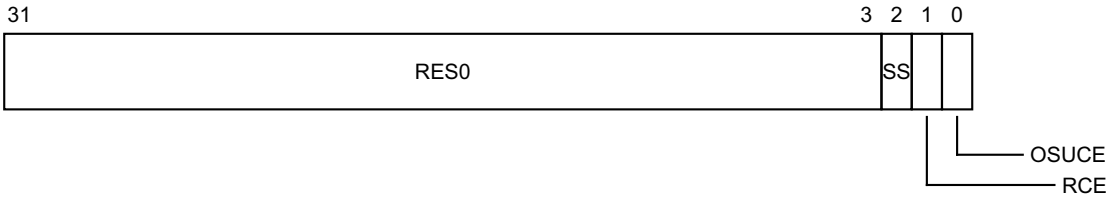
EDECR is in the Debug power domain.

Attributes

EDECR is a 32-bit register.

Field descriptions

The EDECR bit assignments are:



Bits [31:3]

Reserved, RES0.

SS, bit [2]

Halting step enable. Possible values of this field are:

`0` Halting step debug event disabled.

`1` Halting step debug event enabled.

If the value of EDECR.SS is changed to 1 when the PE is in Non-debug state, behavior is CONSTRAINED UNPREDICTABLE as described in *Setting the value of EDECR.SS to 1 when not in Debug state* on page K1-5380.

When this register has an architecturally-defined reset value, this field resets to `0`.

RCE, bit [1]

Reset catch enable. Possible values of this field are:

`0` Reset catch debug event disabled.

`1` Reset catch debug event enabled.

When this register has an architecturally-defined reset value, this field resets to `0`.

OSUCE, bit [0]

OS unlock catch enabled. Possible values of this field are:

`0` OS unlock catch debug event disabled.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

1 OS unlock catch debug event enabled.

When this register has an architecturally-defined reset value, this field resets to `0`.

Accessing the EDECR:

EDECR can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0x024`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.27 EDESR, External Debug Event Status Register

The EDESR characteristics are:

Purpose

Indicates the status of internally pending Halting debug events.

Usage constraints

This register is accessible as follows:

Off	DLK	SLK	Default
Error	Error	RO	RW

If a request to clear a pending Halting debug event is received at or about the time when halting becomes allowed, it is CONSTRAINED UNPREDICTABLE whether the event is taken.

If Core power is removed while a Halting debug event is pending, it is lost. However, it might become pending again when the Core is powered back on and Cold reset.

Configurations

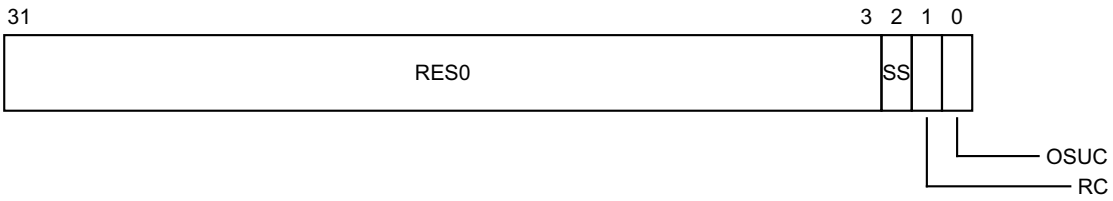
EDESR is in the Core power domain.

Attributes

EDESR is a 32-bit register.

Field descriptions

The EDESR bit assignments are:



Bits [31:3]

Reserved, RES0.

SS, bit [2]

Halting step debug event pending. Possible values of this field are:

`0` Reading this means that a Halting step debug event is not pending. Writing this means no action.

`1` Reading this means that a Halting step debug event is pending. Writing this clears the pending Halting step debug event.

When this register has an architecturally-defined reset value, this field resets to the value of EDECR.SS.

RC, bit [1]

Reset catch debug event pending. Possible values of this field are:

`0` Reading this means that a Reset catch debug event is not pending. Writing this means no action.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

`1` Reading this means that a Reset catch debug event is pending. Writing this clears the pending Reset catch debug event.

When this register has an architecturally-defined reset value, this field resets to the value of EDECR.RCE.

OSUC, bit [0]

OS unlock debug event pending. Possible values of this field are:

`0` Reading this means that an OS unlock catch debug event is not pending. Writing this means no action.

`1` Reading this means that an OS unlock catch debug event is pending. Writing this clears the pending OS unlock catch debug event.

When this register has an architecturally-defined reset value, this field resets to `0`.

Accessing the EDESR:

EDESR can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0x020`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.28 EDITCTRL, External Debug Integration mode Control register

The EDITCTRL characteristics are:

Purpose

Enables the external debug to switch from its default mode into integration mode, where test software can control directly the inputs and outputs of the PE, for integration testing or topology detection.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	Default
IMP DEF	IMP DEF	IMP DEF	RW

Configurations

It is IMPLEMENTATION DEFINED whether EDITCTRL is in the Core power domain or in the Debug power domain.

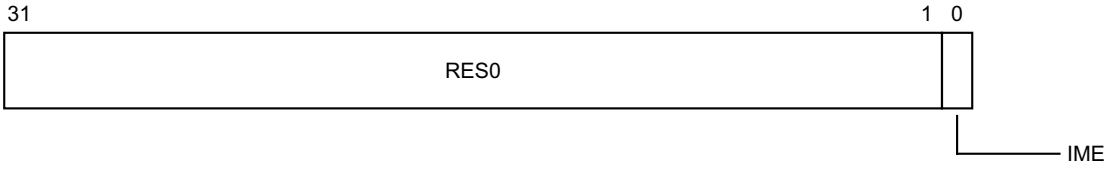
EDITCTRL is optional to implement in the external register interface.

Attributes

EDITCTRL is a 32-bit register.

Field descriptions

The EDITCTRL bit assignments are:



Bits [31:1]

Reserved, RES0.

IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

`0` Normal operation.

`1` Integration mode enabled.

When this register has an architecturally-defined reset value, this field resets to `0`.

Accessing the EDITCTRL:

EDITCTRL can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xF00`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.29 EDITR, External Debug Instruction Transfer Register

The EDITR characteristics are:

Purpose

Used in Debug state for passing instructions to the PE for execution.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	WI	WO

If EDSCR.ITE == 0 when the PE exits Debug state on receiving a Restart request trigger event, the behavior of any instruction issued through the ITR in Normal access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state before the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

Configurations

EDITR is in the Core power domain.

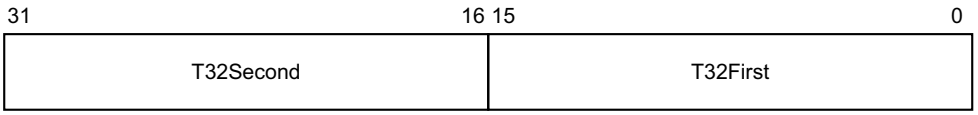
Attributes

EDITR is a 32-bit register.

Field descriptions

The EDITR bit assignments are:

When in AArch32 state:



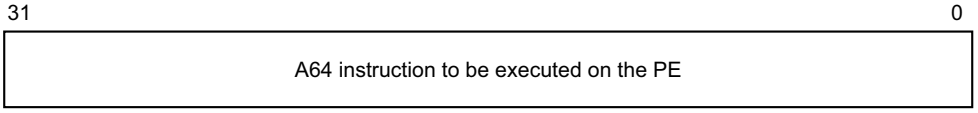
T32Second, bits [31:16]

Second halfword of the T32 instruction to be executed on the PE.

T32First, bits [15:0]

First halfword of the T32 instruction to be executed on the PE.

When in AArch64 state:



Bits [31:0]

A64 instruction to be executed on the PE.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the EDITR:

EDITR can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x084

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.30 EDLAR, External Debug Lock Access Register

The EDLAR characteristics are:

Purpose

Allows or disallows access to the external debug registers through a memory-mapped interface.

Usage constraints

This register is accessible as follows:

Default
WO

Configurations

EDLAR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software lock can be implemented as part of CoreSight compliance.

EDLAR ignores writes if the Software lock is not implemented and ignores writes for other accesses to the external debug interface.

The Software lock provides a lock to prevent memory-mapped writes to the debug registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the debug registers. It does not, and cannot, prevent all accidental or malicious damage.

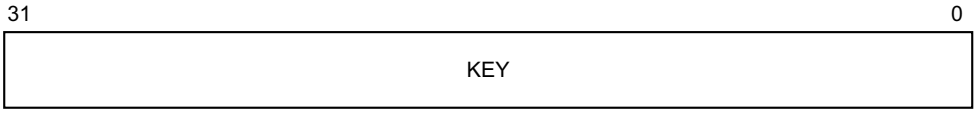
Software uses EDLAR to set or clear the lock, and EDLSR to check the current status of the lock.

Attributes

EDLAR is a 32-bit register.

Field descriptions

The EDLAR bit assignments are:



KEY, bits [31:0]

Lock Access control. Writing the key value `0xC5ACCE55` to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

Accessing the EDLAR:

EDLAR can be accessed through the memory-mapped interface:

Component	Offset
Debug	`0xFB0`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.31 EDLSR, External Debug Lock Status Register

The EDLSR characteristics are:

Purpose

Indicates the current status of the software lock for external debug registers.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

EDLSR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software lock can be implemented as part of CoreSight compliance.

EDLSR is RAZ if the Software lock is not implemented and is RAZ for other accesses to the external debug interface.

The Software lock provides a lock to prevent memory-mapped writes to the debug registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the debug registers. It does not, and cannot, prevent all accidental or malicious damage.

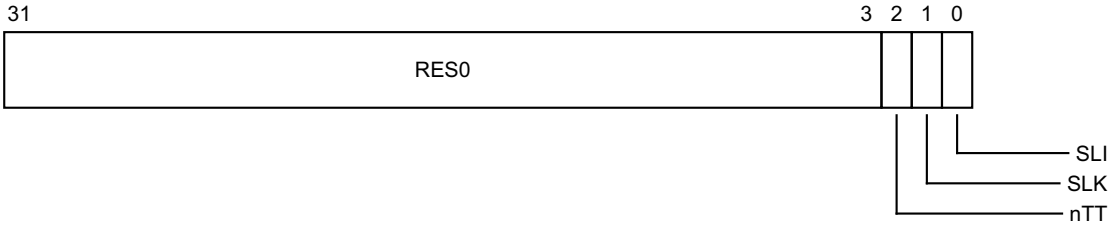
Software uses EDLAR to set or clear the lock, and EDLSR to check the current status of the lock.

Attributes

EDLSR is a 32-bit register.

Field descriptions

The EDLSR bit assignments are:



Bits [31:3]

Reserved, RES0.

nTT, bit [2]

Not thirty-two bit access required. RAZ.

SLK, bit [1]

Software lock status for this component. For an access to LSR that is not a memory-mapped access, or when the software lock is not implemented, this field is RES0.

For memory-mapped accesses when the software lock is implemented, possible values of this field are:

`0` Lock clear. Writes are permitted to this component's registers.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

`1` Lock set. Writes to this component's registers are ignored, and reads have no side effects.

When this register has an architecturally-defined reset value, this field resets to `1`.

SLI, bit [0]

Software lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are:

`0` Software lock not implemented or not memory-mapped access.

`1` Software lock implemented and memory-mapped access.

Accessing the EDLSR:

EDLSR can be accessed through the memory-mapped interface:

Component	Offset
Debug	`0xFB4`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.32 EDPCSR, External Debug Program Counter Sample Register

The EDPCSR characteristics are:

Purpose

Holds a sampled instruction address value.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RO

Configurations

EDPCSR is in the Core power domain.

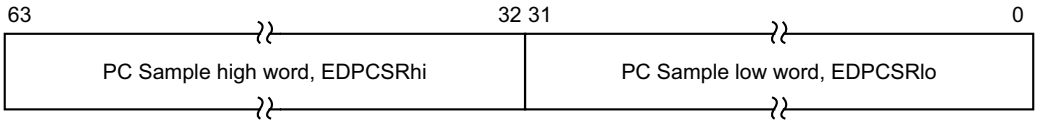
EDPCSR is optional to implement in the external register interface.

Attributes

EDPCSR is a 64-bit register.

Field descriptions

The EDPCSR bit assignments are:



Bits [63:32]

PC Sample high word, EDPCSRhi. If EDVIDSR.HV == 0 then this field is RAZ, otherwise bits [63:32] of the sampled PC.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bits [31:0]

PC Sample low word, EDPCSRlo. Bits [31:0] of the sampled instruction address value. Reading EDPCSRlo has the side-effect of updating EDCIDSR, EDVIDSR, and EDPCSRhi. However:

- If the PE is in Debug state, or Sample-based profiling is prohibited, EDPCSRlo reads as `0xFFFFFFFF` and EDCIDSR, EDVIDSR, and EDPCSRhi become UNKNOWN.
- If the PE is in Reset state, the sampled value is unknown and EDCIDSR, EDVIDSR and EDPCSRhi become UNKNOWN.
- If no instruction has been retired since the PE left Reset state, Debug state, or a state where Non-invasive debug is not permitted, the sampled value is UNKNOWN and EDCIDSR, EDVIDSR, and EDPCSRhi become UNKNOWN.
- For a read of EDPCSRlo from the memory-mapped interface, if EDLSR.SLK == 1, meaning the Software Lock is locked, then the access has no side-effects. That is, EDCIDSR, EDVIDSR, and EDPCSRhi are unchanged.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the EDPCSR:

EDPCSR[31:0] can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x0A0

EDPCSR[63:32] can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x0AC

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.33 EDPFR, External Debug Processor Feature Register

The EDPFR characteristics are:

Purpose

Provides additional information about implemented PE features in AArch64.

Usage constraints

This register is accessible as follows:

Default
RO

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page D7-1806.

Configurations

External register EDPFR is architecturally mapped to AArch64 System register ID_AA64PFR0_EL1.

EDPFR is in the Debug power domain.

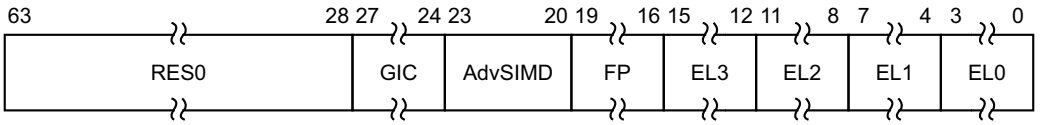
If AArch64 is supported at any Exception level, bits [27:0] take the value of the System register ID_AA64PFR0_EL1[27:0]. Otherwise, bits [27:16] have the same definition as ID_AA64PFR0_EL1, even though AArch64 is not implemented, and bits [15:0] are zero.

Attributes

EDPFR is a 64-bit register.

Field descriptions

The EDPFR bit assignments are:



Bits [63:28]

Reserved, RES0.

GIC, bits [27:24]

System register GIC interface support. Defined values are:

0000 No System register interface to the GIC is supported.

0001 System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported.

0010 System register interface to version 3.0 of the GIC CPU interface is supported.

All other values are reserved.

AdvSIMD, bits [23:20]

Advanced SIMD. Defined values are:

0000 Advanced SIMD is implemented.

1111 Advanced SIMD is not implemented.

All other values are reserved.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

FP, bits [19:16]

Floating-point. Defined values are:

`0000` Floating-point is implemented.

`1111` Floating-point is not implemented.

All other values are reserved.

EL3, bits [15:12]

AArch64 EL3 Exception level handling. Defined values are:

`0000` EL3 is not implemented or cannot be executed in AArch64 state.

`0001` EL3 can be executed in AArch64 state only.

`0010` EL3 can be executed in either AArch64 or AArch32 state.

When the value of EDAA32PFR.EL3 is non-zero, this field must be `0000`.

All other values are reserved.

Note

EDAA32PFR is only accessible in an AArch32-only implementation.

EL2, bits [11:8]

AArch64 EL2 Exception level handling. Defined values are:

`0000` EL2 is not implemented or cannot be executed in AArch64 state.

`0001` EL2 can be executed in AArch64 state only.

`0010` EL2 can be executed in either AArch64 or AArch32 state.

When the value of EDAA32PFR.EL2 is non-zero, this field must be `0000`.

All other values are reserved.

Note

EDAA32PFR is only accessible in an AArch32-only implementation.

EL1, bits [7:4]

AArch64 EL1 Exception level handling. Defined values are:

`0000` EL1 can be executed in AArch32 state only.

`0001` EL1 can be executed in AArch64 state only.

`0010` EL1 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

EL0, bits [3:0]

AArch64 EL0 Exception level handling. Defined values are:

`0000` EL0 can be executed in AArch32 state only.

`0001` EL0 can be executed in AArch64 state only.

`0010` EL0 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

Non-Confidential - Beta

Accessing the EDPFR:

EDPFR[31:0] can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD20

EDPFR[63:32] can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD24

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.34 EDPIDR0, External Debug Peripheral Identification Register 0

The EDPIDR0 characteristics are:

Purpose

Provides information to identify an external debug component.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

EDPIDR0 is in the Debug power domain.

EDPIDR0 is optional to implement in the external register interface.

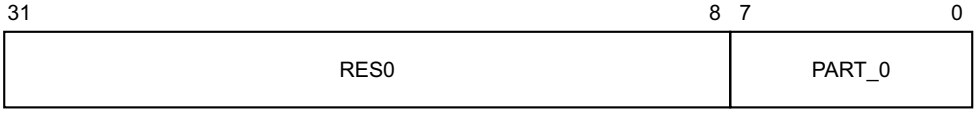
This register is required for CoreSight compliance.

Attributes

EDPIDR0 is a 32-bit register.

Field descriptions

The EDPIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PART_0, bits [7:0]

Part number, least significant byte.

Accessing the EDPIDR0:

EDPIDR0 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFE0

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.35 EDPIDR1, External Debug Peripheral Identification Register 1

The EDPIDR1 characteristics are:

Purpose

Provides information to identify an external debug component.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

EDPIDR1 is in the Debug power domain.

EDPIDR1 is optional to implement in the external register interface.

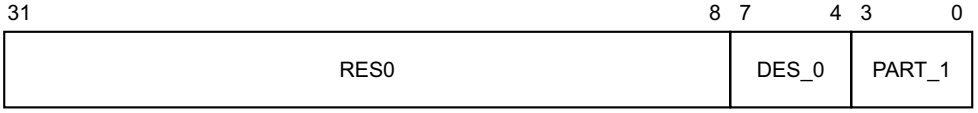
This register is required for CoreSight compliance.

Attributes

EDPIDR1 is a 32-bit register.

Field descriptions

The EDPIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

DES_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is `0b1011`.

PART_1, bits [3:0]

Part number, most significant nibble.

Accessing the EDPIDR1:

EDPIDR1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFE4`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.36 EDPIDR2, External Debug Peripheral Identification Register 2

The EDPIDR2 characteristics are:

Purpose

Provides information to identify an external debug component.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

EDPIDR2 is in the Debug power domain.

EDPIDR2 is optional to implement in the external register interface.

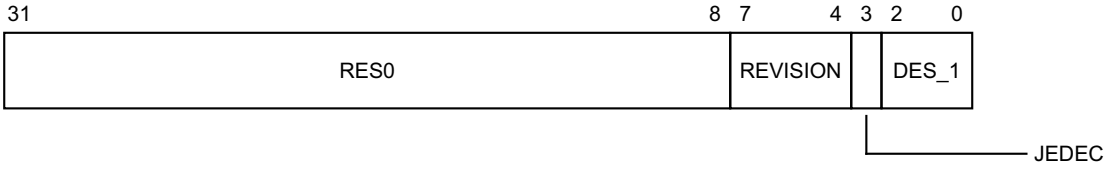
This register is required for CoreSight compliance.

Attributes

EDPIDR2 is a 32-bit register.

Field descriptions

The EDPIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

JEDEC, bit [3]

RAO. Indicates a JEP106 identity code is used.

DES_1, bits [2:0]

Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is `0b011`.

Accessing the EDPIDR2:

EDPIDR2 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFE8`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.37 EDPIDR3, External Debug Peripheral Identification Register 3

The EDPIDR3 characteristics are:

Purpose

Provides information to identify an external debug component.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

EDPIDR3 is in the Debug power domain.

EDPIDR3 is optional to implement in the external register interface.

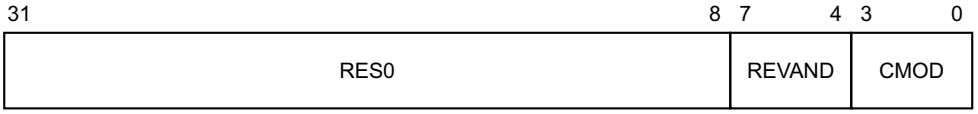
This register is required for CoreSight compliance.

Attributes

EDPIDR3 is a 32-bit register.

Field descriptions

The EDPIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVAND, bits [7:4]

Part minor revision. Parts using EDPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.

CMOD, bits [3:0]

Customer modified. Indicates someone other than the Designer has modified the component.

Accessing the EDPIDR3:

EDPIDR3 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFEC

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.38 EDPIDR4, External Debug Peripheral Identification Register 4

The EDPIDR4 characteristics are:

Purpose

Provides information to identify an external debug component.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

EDPIDR4 is in the Debug power domain.

EDPIDR4 is optional to implement in the external register interface.

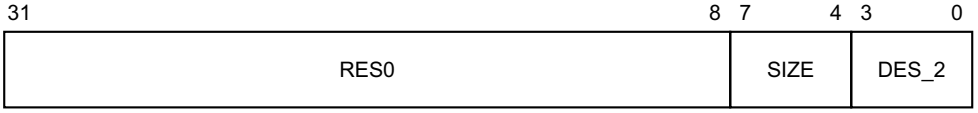
This register is required for CoreSight compliance.

Attributes

EDPIDR4 is a 32-bit register.

Field descriptions

The EDPIDR4 bit assignments are:



Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. RAZ. Log_2 of the number of 4KB pages from the start of the component to the end of the component ID registers.

DES_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is `0b0100`.

Accessing the EDPIDR4:

EDPIDR4 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFD0`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.39 EDPRCR, External Debug Power/Reset Control Register

The EDPRCR characteristics are:

Purpose

Controls the PE functionality related to powerup, reset, and powerdown.

Usage constraints

Accessing this register depends on which field is being accessed; see the register field descriptions for the states that they are accessible in.

Configurations

EDPRCR contains fields that are in the Core power domain and fields that are in the Debug power domain.

Bit [0] of this register is mapped to DBGPRCR.CORENPDRQ, bit [0] of the AArch32 view of this register.

Bit [0] of this register is mapped to DBGPRCR_EL1.CORENPDRQ, bit [0] of the AArch64 view of this register.

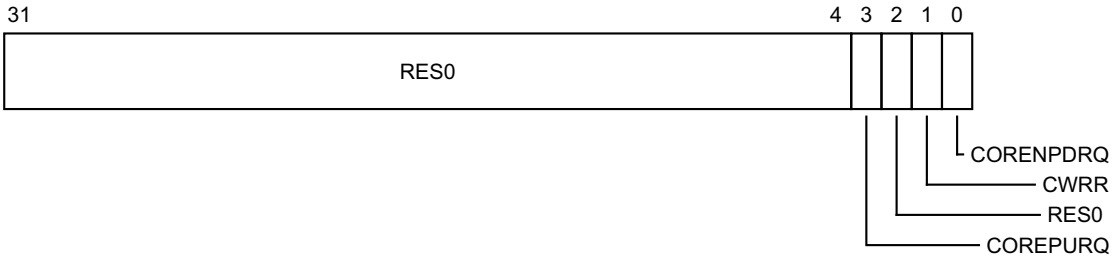
The other bits in these registers are not mapped to each other.

Attributes

EDPRCR is a 32-bit register.

Field descriptions

The EDPRCR bit assignments are:



Bits [31:4]

Reserved, RES0.

COREPURQ, bit [3]

Core powerup request. Allows a debugger to request that the power controller power up the core, enabling access to the debug register in the Core power domain. The actions on writing to this bit are:

`0` Do not request power up of the Core power domain.

`1` Request power up of the Core power domain, and emulation of powerdown.

In an implementation that includes the recommended external debug interface, this bit drives the DBGPWRUPREQ signal.

This bit can be read and written when the Core power domain is powered off.

The power controller must not allow the Core power domain to switch off while this bit is one.

When this register has an architecturally-defined reset value, this field resets to `0`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

This field is accessible as shown below:

SLK	Default
RO	RW

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4824. The priority at which each condition applies is from highest priority on the left to lowest on the right.

Bit [2]

Reserved, RES0.

CWRR, bit [1]

Warm reset request. Write only bit that reads as zero. The actions on writing to this bit are:

`0` No action.

`1` Request Warm reset.

The PE ignores writes to this bit if any of the following are the case:

- ExternalInvasiveDebugEnabled() == FALSE, EL3 is not implemented, and the implemented Security state is Non-Secure state.
- ExternalSecureInvasiveDebugEnabled() == FALSE and one of the following is true:
  - EL3 is implemented.
  - The implemented Security state is Secure state.
- The Core power domain is either completely off or in a low-power state where the Core power domain registers cannot be accessed.
- DoubleLockStatus() == TRUE (OS Double Lock is set).
- OSLSR.OSLK == 1 (OS lock is locked).

In an implementation that includes the recommended external debug interface, this bit drives the DBGRSTREQ signal.

When a write to this bit initiates a Warm Reset, the extent of the reset is IMPLEMENTATION DEFINED, but must be one of:

- The request is ignored.
- Only this PE is Warm reset.
- This PE and other components of the system, possibly including other PEs, are Warm reset.

Note

Although the ARM architecture permits the first option from the above list, ARM recommends that either of the other options is implemented.

When this register has an architecturally-defined reset value, this field resets to `0`.

This field is accessible as shown below:

Off	DLK	OSLK	SLK	Default
WI	WI	WI	WI	WO

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4824. The priority at which each condition applies is from highest priority on the left to lowest on the right.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

CORENPDRQ, bit [0]

Core no powerdown request. Requests emulation of powerdown. Possible values of this bit are:

`0` If the system responds to a powerdown request, it powers down Core power domain.

`1` If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

This bit is UNKNOWN, and the PE ignores writes to this bit if any of the following are the case:

- The Core power domain is either completely off or in a low-power state where the Core power domain registers cannot be accessed.
- DoubleLockStatus() == TRUE (OS Double Lock is set).
- OSLSR.OSLK == 1 (OS lock is locked).

When this register has an architecturally-defined reset value, this field resets to the value of EDPRCR.COREPURQ.

This field is accessible as shown below:

Off	DLK	OSLK	SLK	Default
WI	WI	WI	RO	RW

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4824. The priority at which each condition applies is from highest priority on the left to lowest on the right.

Accessing the EDPRCR:

EDPRCR can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0x310`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.40 EDPRSR, External Debug Processor Status Register

The EDPRSR characteristics are:

Purpose

Holds information about the reset and powerdown state of the PE.

Usage constraints

Accessing this register depends on which field is being accessed; see the register field descriptions for the states that they are accessible in.

If the Core power domain is powered up (EDPRSR.PU == 1), then following a read of EDPRSR:

- If DoubleLockStatus() == FALSE, then:
  - EDPRSR.{SDR, SPMAD, SDAD, SPD} are cleared to 0.
  - EDPRSR.SR is cleared to 0 if the non-debug logic of the PE is not in reset state (EDPRSR.R == 0).
- Otherwise it is CONSTRAINED UNPREDICTABLE whether or not this clearing occurs.

If the Core power domain is powered down (EDPRSR.PU == 0), then:

- EDPRSR.{SDR, SPMAD, SDAD, SR} are all UNKNOWN, and are either reset or restored on being powered up.
- EDPRSR.SPD is not cleared following a read of EDPRSR. See the SPD bit description for more information.

Configurations

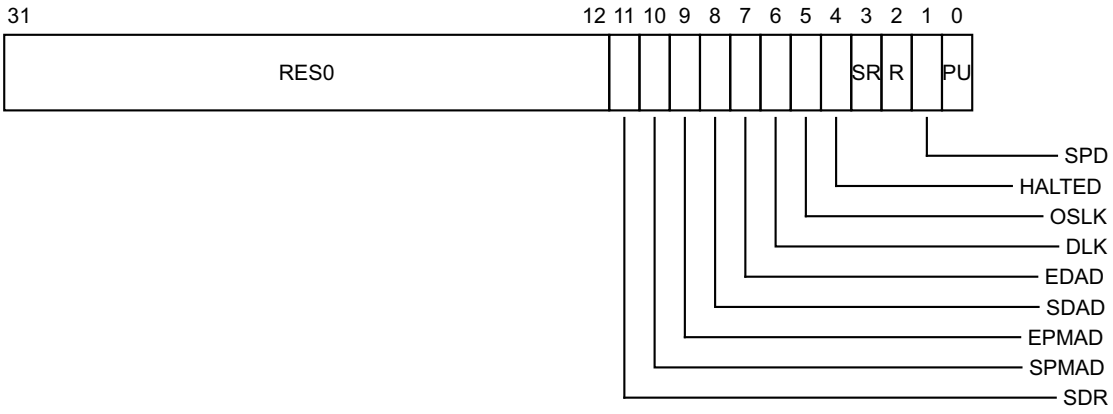
EDPRSR contains fields that are in the Core power domain and fields that are in the Debug power domain.

Attributes

EDPRSR is a 32-bit register.

Field descriptions

The EDPRSR bit assignments are:



Bits [31:12]

Reserved, RES0.

SDR, bit [11]

Sticky debug restart. Set to 1 when the PE exits Debug state.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

This bit is UNKNOWN on reads if any of the following are true:

- DoubleLockStatus() == TRUE (EDPRSR.DLK == 1). The OS double-lock is locked.
- EDPRSR.R == 1. The PE is in Reset state.
- CorePoweredUp() == FALSE (EDPRSR.PU == 0). The Core power domain is powered down.

Otherwise permitted values are:

`0` The PE has not restarted since EDPRSR was last read.

`1` The PE has restarted since EDPRSR was last read.

Note

If a reset occurs when the PE is in Debug state, the PE exits Debug state. SDR is UNKNOWN on Warm reset, meaning a debugger must also use the SR bit to infer the PE has left Debug state in this case.

If DoubleLockStatus() == FALSE then following a read of EDPRSR, this bit clears to 0. Otherwise it is CONSTRAINED UNPREDICTABLE whether or not this clearing occurs.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	SLK	Default
UNK	UNK	RO	RC

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4824. The priority at which each condition applies is from highest priority on the left to lowest on the right.

SPMAD, bit [10]

Sticky EPMAD error. Set to 1 if an external debug interface access to a Performance Monitors register returns an error because AllowExternalPMUAccess() == FALSE.

This bit is UNKNOWN on reads if any of EDPRSR.{DLK, OSLK, R} is 1, or EDPRSR.PU is 0.

Otherwise permitted values are:

`0` No accesses to the external Performance Monitors registers have failed since EDPRSR was last read.

`1` At least one access to the external Performance Monitors registers has failed since EDPRSR was last read.

If DoubleLockStatus() == FALSE then following a read of EDPRSR, this bit clears to 0. Otherwise it is CONSTRAINED UNPREDICTABLE whether or not this clearing occurs.

When this register has an architecturally-defined reset value, this field resets to `0`.

This field is accessible as shown below:

Off	DLK	SLK	Default
UNK	UNK	RO	RC

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4824. The priority at which each condition applies is from highest priority on the left to lowest on the right.

EPMAD, bit [9]

External Performance Monitors access disable status.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

This bit is UNKNOWN on reads if any of EDPRSR.{DLK, OSLK, R} is 1, or EDPRSR.PU is 0.

Otherwise permitted values are:

`0` External Performance Monitors access enabled. AllowExternalPMUAccess() == TRUE.

`1` External Performance Monitors access disabled. AllowExternalPMUAccess() == FALSE.

If external performance monitors access is not implemented, EPMAD is RAO.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	Default
UNK	UNK	RO

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4824. The priority at which each condition applies is from highest priority on the left to lowest on the right.

SDAD, bit [8]

Sticky EDAD error. Set to 1 if an external debug interface access to a debug register returns an error because AllowExternalDebugAccess() == FALSE.

This bit is UNKNOWN on reads if any of the following are true:

- Either of EDPRSR.{DLK, R} is 1.
- EDPRSR.PU is 0.
- EDPRSR.OSLK is 1 and external debug writes to OSLAR_EL1 do not return an error when AllowExternalDebugAccess() == FALSE.

Otherwise permitted values are:

`0` No accesses to the external debug registers have failed since EDPRSR was last read.

`1` At least one access to the external debug registers has failed since EDPRSR was last read.

If DoubleLockStatus() == FALSE then following a read of EDPRSR, this bit clears to 0. Otherwise it is CONSTRAINED UNPREDICTABLE whether or not this clearing occurs.

When this register has an architecturally-defined reset value, this field resets to `0`.

This field is accessible as shown below:

Off	DLK	SLK	Default
UNK	UNK	RO	RC

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4824. The priority at which each condition applies is from highest priority on the left to lowest on the right.

EDAD, bit [7]

External debug access disable status.

This bit is UNKNOWN on reads if any of the following are true:

- Either of EDPRSR.{DLK, R} is 1.
- EDPRSR.PU is 0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- EDPRSR.OSLK is 1 and external debug writes to OSLAR_EL1 do not return an error when AllowExternalDebugAccess() == FALSE.

Otherwise permitted values are:

`0` External debug access enabled. AllowExternalDebugAccess() == TRUE.

`1` External debug access disabled. AllowExternalDebugAccess() == FALSE.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	EDAD	Default
UNK	UNK	RAO	RAZ

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4824. The priority at which each condition applies is from highest priority on the left to lowest on the right.

DLK, bit [6]

OS Double Lock status bit. Returns the result of the pseudocode function DoubleLockStatus().

This bit is UNKNOWN on reads if EDPRSR.PU is 0.

Otherwise reads as zero if any of the following are true, that is when DoubleLockStatus() == FALSE:

- OSDLR_EL1.DLK == 0.
- DBGPRCR_EL1.CORENPDRQ == 1.
- The PE is in Debug state.

If the Core power domain is powered up and DoubleLockStatus() == TRUE, it is IMPLEMENTATION DEFINED whether:

- EDPRSR.PU reads as 0, EDPRSR.DLK reads as 1, and EDPRSR.SPD is UNKNOWN.
- EDPRSR.PU reads as 1, EDPRSR.DLK is UNKNOWN, and EDPRSR.SPD reads as 0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	Default
UNK	RAO	RAZ

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4824. The priority at which each condition applies is from highest priority on the left to lowest on the right.

OSLK, bit [5]

OS lock status bit.

This bit is UNKNOWN on reads if either of EDPRSR.{DLK, R} is 1 or EDPRSR.PU is 0.

A read of this bit returns the value of OSLSR_EL1.OSLK.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

This field is accessible as shown below:

Off	DLK	OSLK	Default
UNK	UNK	RAO	RAZ

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4824. The priority at which each condition applies is from highest priority on the left to lowest on the right.

HALTED, bit [4]

Halted status bit.

This bit is UNKNOWN on reads if EDPRSR.PU is 0.

Otherwise permitted values are:

`0` EDSCR.STATUS is `0b000010` (PE in Non-debug state).

`1` EDSCR.STATUS is not `0b000010`.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	Default
UNK	RAZ	RO

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4824. The priority at which each condition applies is from highest priority on the left to lowest on the right.

SR, bit [3]

Sticky core reset status bit.

This bit is UNKNOWN on reads if EDPRSR.DLK is 1 or EDPRSR.PU is 0.

Otherwise permitted values are:

`0` The non-debug logic of the PE is not in reset state and has not been reset since the last time EDPRSR was read.

`1` The non-debug logic of the PE is in reset state or has been reset since the last time EDPRSR was read.

If DoubleLockStatus() == FALSE then following a read of EDPRSR, this bit clears to 0 if the non-debug logic of the PE is not in reset state. Otherwise it is CONSTRAINED UNPREDICTABLE whether or not this clearing occurs.

When this register has an architecturally-defined reset value, this field resets to `1`.

This field is accessible as shown below:

Off	DLK	SLK	Default
UNK	UNK	RO	RC

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4824. The priority at which each condition applies is from highest priority on the left to lowest on the right.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

R, bit [2]

Core reset status bit.

This bit is UNKNOWN on reads if either EDPRSR.DLK is 1 or EDPRSR.PU is 0.

Otherwise permitted values are:

`0` The non-debug logic of the PE is not in reset state.

`1` The non-debug logic of the PE is in reset state.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	Default
UNK	UNK	RO

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4824. The priority at which each condition applies is from highest priority on the left to lowest on the right.

SPD, bit [1]

Sticky core powerdown status bit.

This bit is UNKNOWN on reads if both EDPRSR.DLK and EDPRSR.PU are 1.

Otherwise, permitted values are:

`0` If the Core power domain is in a low-power or powerdown state (EDPRSR.PU is 0), it is not known whether the state of the debug registers in the Core power domain is lost.

If the Core power domain is in a powerup state (EDPRSR.PU is 1), the state of the debug registers in the Core power domain has not been lost.

`1` The state of the debug registers in the Core power domain is lost.

If DoubleLockStatus() == FALSE and the PE is not in the powerdown state, then following a read of EDPRSR, this bit clears to 0. Otherwise it is CONSTRAINED UNPREDICTABLE whether or not this clearing occurs.

If DoubleLockStatus() == TRUE and the PE is not in the powerdown state, it is CONSTRAINED UNPREDICTABLE whether or not this clearing occurs.

There are two logical states for the Core power domain when EDPRSR.PU is 0:

`Retention` The state of the debug registers, including EDPRSR.SPD, in the Core power domain is preserved, and restored on leaving retention state.

`Powerdown` The state of the debug registers in the Core power domain is lost, and a Cold reset is asserted on leaving powerdown state.

In these states, EDPRSR.SPD is not cleared following a read of EDPRSR, and it is IMPLEMENTATION DEFINED whether:

- EDPRSR.SPD shows whether the state of the debug registers in the Core power domain has been lost since the last time EDPRSR was read when the Core power domain was powered up. That is:
  - While in the powerdown state, EDPRSR.SPD is RAO, as the state of the debug registers has been lost.
  - While in the retention state, the value of EDPRSR.EPD is unchanging and shows whether the state of the debug registers was lost before entering retention state. This does not allow EDPRSR.SPD to be fixed RAO in the retention state, as the state of the debug registers in the Core power domain is not lost by entering this state. EDPRSR.SPD can read as either 0 or 1.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- EDPRSR.SPD reads-as-zero, and:
  - On leaving the powerdown state, EDPRSR.SPD is set to 1, as the state of the debug registers has been lost.
  - On leaving the retention state, EDPRSR.SPD reverts to the value it had on entering retention state.

ARM recommends that an implementation make EDPRSR.SPD fixed RAO when in the powerdown state, particularly if it does not support a low-power retention state.

When this register has an architecturally-defined reset value, this field resets to 1.

This field is accessible as shown below:

Off	DLK	SLK	Default
RO	UNK	RO	RC

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4824. The priority at which each condition applies is from highest priority on the left to lowest on the right.

PU, bit [0]

Core powerup status bit. Indicates whether the Core power domain debug registers can be accessed.

The value of EDPRSR.PU is IMPLEMENTATION DEFINED when the OS double-lock is locked. See the description of DLK for more information.

Otherwise, permitted values are:

0 Core is in a low-power or powerdown state where the debug registers cannot be accessed.

1 Core is in a powerup state where the debug registers can be accessed.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field is accessible as shown below:

Off	Default
RAZ	RAO

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4824. The priority at which each condition applies is from highest priority on the left to lowest on the right.

Accessing the EDPRSR:

EDPRSR can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x314

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.41 EDRCR, External Debug Reserve Control Register

The EDRCR characteristics are:

Purpose

This register is used to allow imprecise entry to Debug state and clear sticky bits in EDSCR.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	WI	WO

Configurations

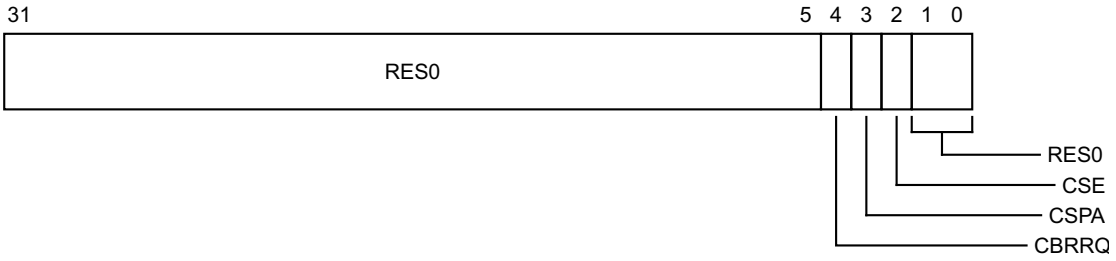
EDRCR is in the Core power domain.

Attributes

EDRCR is a 32-bit register.

Field descriptions

The EDRCR bit assignments are:



Bits [31:5]

Reserved, RES0.

CBRRQ, bit [4]

Allow imprecise entry to Debug state. The actions on writing to this bit are:

0 No action.

1 Allow imprecise entry to Debug state, for example by canceling pending bus accesses.

Setting this bit to 1 allows a debugger to request imprecise entry to Debug state. An External Debug Request debug event must be pending before the debugger sets this bit to 1.

This feature is optional. If this feature is not implemented, writes to this bit are ignored.

CSPA, bit [3]

Clear Sticky Pipeline Advance. This bit is used to clear the EDSCR.PipeAdv bit to 0. The actions on writing to this bit are:

0 No action.

1 Clear the EDSCR.PipeAdv bit to 0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

CSE, bit [2]

Clear Sticky Error. Used to clear the EDSCR cumulative error bits to 0. The actions on writing to this bit are:

`0` No action.

`1` Clear the EDSCR.{TXU, RXO, ERR} bits, and, if the PE is in Debug state, the EDSCR.ITO bit, to 0.

Bits [1:0]

Reserved, RES0.

Accessing the EDRCR:

EDRCR can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0x090`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.42 EDSCR, External Debug Status and Control Register

The EDSCR characteristics are:

Purpose

Main control register for the debug implementation.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

Configurations

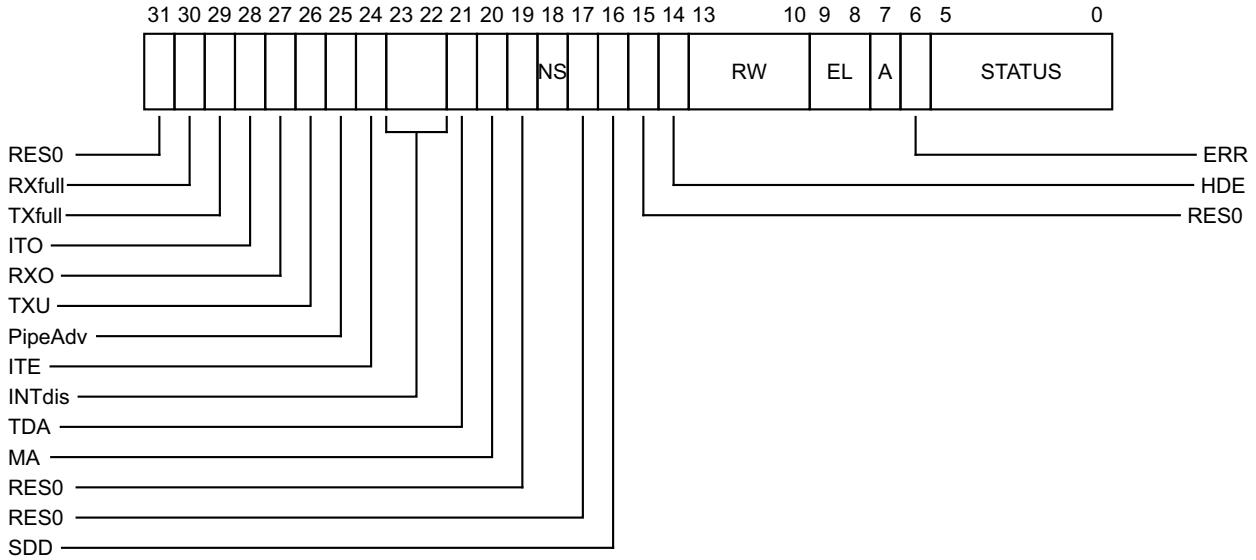
EDSCR is in the Core power domain.

Attributes

EDSCR is a 32-bit register.

Field descriptions

The EDSCR bit assignments are:



Bit [31]

Reserved, RES0.

RXfull, bit [30]

DTRRX full. This bit is RO.

When this register has an architecturally-defined reset value, this field resets to `0`.

TXfull, bit [29]

DTRTX full. This bit is RO.

When this register has an architecturally-defined reset value, this field resets to `0`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

ITO, bit [28]

EDITR overrun. This bit is RO.

If the PE is in Non-debug state, this bit is UNKNOWN. ITO is set to 0 on entry to Debug state.

RXO, bit [27]

DTRRX overrun. This bit is RO.

When this register has an architecturally-defined reset value, this field resets to `0`.

TXU, bit [26]

DTRTX underrun. This bit is RO.

When this register has an architecturally-defined reset value, this field resets to `0`.

PipeAdv, bit [25]

Pipeline advance. Read-only. Set to 1 every time the PE pipeline retires one or more instructions. Cleared to 0 by a write to EDRCR.CSPA.

The architecture does not define precisely when this bit is set to 1. It requires only that this happen periodically in Non-debug state to indicate that software execution is progressing.

ITE, bit [24]

ITR empty. This bit is RO.

If the PE is in Non-debug state, this bit is UNKNOWN. It is always valid in Debug state.

INTdis, bits [23:22]

Interrupt disable. Disables taking interrupts (including virtual interrupts and System Error interrupts) in Non-Debug state.

If external invasive debug is disabled, the value of this field is ignored.

If external invasive debug is enabled, the possible values of this field are:

`00` Do not disable interrupts

`01` Disable interrupts taken to Non-secure EL1.

`10` Disable interrupts taken only to Non-secure EL1 and Non-secure EL2. If external secure invasive debug is enabled, also disable interrupts taken to Secure EL1.

`11` Disable interrupts taken only to Non-secure EL1 and Non-secure EL2. If external secure invasive debug is enabled, also disable all other interrupts.

The value of INTdis does not affect whether an interrupt is a WFI wake-up event, but can mask an interrupt as a WFE wake-up event.

If EL3 and EL2 are not implemented, INTdis[0] is RO and reads the same value as INTdis[1], meaning only the values `00` and `11` can be selected.

When this register has an architecturally-defined reset value, this field resets to `0`.

TDA, bit [21]

Traps accesses to the following Debug System registers:

- AArch64: DBGBCR<n>_EL1, DBGBVR<n>_EL1, DBGWCR<n>_EL1, DBGWVR<n>_EL1.
- AArch32: DBGBCR<n>, DBGBVR<n>, DBGBXVR<n>, DBGWCR<n>, DBGWVR<n>.

The possible values of this field are:

`0` Accesses to Debug System registers do not generate a Software Access debug event.

`1` Accesses to Debug System registers generate a Software Access debug event, if OSLSR.OSLK is 0 and if halting is allowed.

When this register has an architecturally-defined reset value, this field resets to `0`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

MA, bit [20]

Memory access mode. Controls use of memory-access mode for accessing EDITR and the DCC. This bit is ignored if in Non-debug state and set to zero on entry to Debug state.

Possible values of this field are:

`0` Normal access mode.

`1` Memory access mode.

When this register has an architecturally-defined reset value, this field resets to `0`.

Bit [19]

Reserved, RES0.

NS, bit [18]

Non-secure status. Read-only. When in Debug state, gives the current Security state:

`0` Secure state, IsSecure() == TRUE.

`1` Non-secure state, IsSecure() == FALSE.

In Non-debug state, this bit is UNKNOWN.

Bit [17]

Reserved, RES0.

SDD, bit [16]

Secure debug disabled. This bit is RO.

On entry to Debug state:

- If entering in Secure state, SDD is set to 0.
- If entering in Non-secure state, SDD is set to the inverse of ExternalSecureInvasiveDebugEnabled().

In Debug state, the value of the SDD bit does not change, even if ExternalSecureInvasiveDebugEnabled() changes.

In Non-debug state:

- SDD returns the inverse of ExternalSecureInvasiveDebugEnabled(). If the authentication signals that control ExternalSecureInvasiveDebugEnabled() change, a context synchronization operation is required to guarantee their effect.
- This bit is unaffected by the Security state of the PE.

If EL3 is not implemented and the implementation is Non-secure, this bit is RES1.

Bit [15]

Reserved, RES0.

HDE, bit [14]

Halting debug enable.

When this register has an architecturally-defined reset value, this field resets to `0`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

RW, bits [13:10]

Exception level Execution state status. Read-only. In Debug state, each bit gives the current Execution state of each EL:

RW	Meaning
1111	All Exception levels are using AArch64.
1110	EL0 is using AArch32. All other Exception levels are using AArch64.
110x	EL0 and EL1 are using AArch32. All other Exception levels are using AArch64. Never seen if EL2 is not implemented in the current Security state.
10xx	EL0, EL1, and, if implemented in the current Security state, EL2 are using AArch32. All other Exception levels are using AArch64.
0xxx	All Exception levels are using AArch32.

However:

- The value of 1110 is only permitted at EL0.
- The values 110x are not permitted if either:
  - EL2 is not implemented.
  - EL3 is implemented and SCR_EL3.NS/SCR.NS == 0.
- The values 10xx are not permitted if EL3 is not implemented.

In Non-debug state, this field is RAO.

EL, bits [9:8]

Exception level. Read-only. In Debug state, this gives the current EL of the PE.

In Non-debug state, this field is RAZ.

A, bit [7]

System Error interrupt pending. Read-only. In Debug state, indicates whether a SError interrupt is pending:

- If HCR_EL2.{AMO, TGE} = {1, 0} and in Non-secure EL0 or EL1, a virtual SError interrupt.
- Otherwise, a physical SError interrupt.

0 No SError interrupt pending.

1 SError interrupt pending.

A debugger can read EDSCR to check whether an SError interrupt is pending without having to execute further instructions. A pending SError might indicate data from target memory is corrupted.

UNKNOWN in Non-debug state.

ERR, bit [6]

Cumulative error flag. This field is RO. It is set to 1 following exceptions in Debug state and on any signaled overrun or underrun on the DTR or EDITR.

When this register has an architecturally-defined reset value, this field resets to 0.

STATUS, bits [5:0]

Debug status flags. This field is RO.

The possible values of this field are:

000010 PE is in Non-debug state.

000001 PE is restarting (exiting Debug state).

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

000111	Breakpoint.
010011	External debug request.
011011	Halting step, normal.
011111	Halting step, exclusive.
100011	OS unlock catch.
100111	Reset catch.
101011	Watchpoint.
101111	HLT instruction.
110011	Software access to debug register.
110111	Exception catch.
111011	Halting step, no syndrome.

All other values of STATUS are reserved.

Accessing the EDSCR:

EDSCR can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x088

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.43 EDVIDSR, External Debug Virtual Context Sample Register

The EDVIDSR characteristics are:

Purpose

Contains sampled values captured on reading EDPCSR.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	Default
Error	Error	Error	RO

Configurations

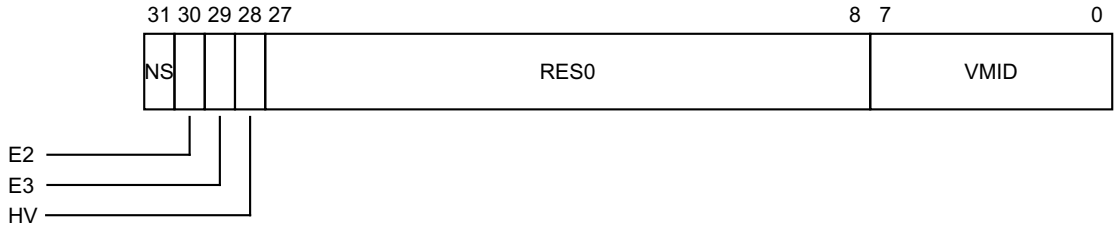
EDVIDSR is in the Core power domain.

Attributes

EDVIDSR is a 32-bit register.

Field descriptions

The EDVIDSR bit assignments are:



NS, bit [31]

Non-secure state sample. Indicates the Security state associated with the most recent EDPCSR sample.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

E2, bit [30]

Exception level 2 status sample. Indicates whether the most recent EDPCSR sample was associated with EL2. If EDVIDSR.NS == 0, this bit is 0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

E3, bit [29]

Exception level 3 status sample. Indicates whether the most recent EDPCSR sample was associated with AArch64 EL3. If EDVIDSR.NS == 1 or the PE was in AArch32 state when EDPCSR was read, this bit is 0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

HV, bit [28]

EDPCSR high half valid. Indicates whether bits [63:32] of the most recent EDPCSR sample are valid. If EDVIDSR.HV == 0, the value of EDPCSR[63:32] is RAZ.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bits [27:8]

Reserved, RES0.

VMID, bits [7:0]

VMID sample. The value of VTTBR_EL2.VMID associated with the most recent EDPCSR sample. If EDVIDSR.NS == 0 or EDVIDSR.E2 == 1, this field is RAZ.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the EDVIDSR:

EDVIDSR can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x0A8

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.44 EDWAR, External Debug Watchpoint Address Register

The EDWAR characteristics are:

Purpose

Contains the virtual data address being accessed when a watchpoint debug event was triggered.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	Default
Error	Error	Error	RO

Configurations

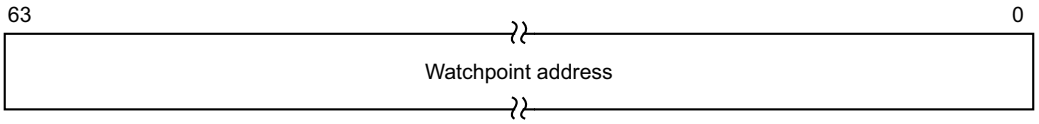
EDWAR is in the Core power domain.

Attributes

EDWAR is a 64-bit register.

Field descriptions

The EDWAR bit assignments are:



Bits [63:0]

Watchpoint address. The virtual data address being accessed when a watchpoint debug event was triggered and caused entry to Debug state.

UNKNOWN if the PE is in Non-debug state, or if Debug state was entered other than for a watchpoint debug event.

The address must be within a naturally-aligned block of memory of power-of-two size no larger than the DC ZVA block size.

Accessing the EDWAR:

EDWAR[31:0] can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x030

EDWAR[63:32] can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x034

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.45 MIDR_EL1, Main ID Register

The MIDR_EL1 characteristics are:

Purpose

Provides identification information for the PE, including an implementer code for the device and a device ID number.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

External register MIDR_EL1 is architecturally mapped to AArch64 System register MIDR_EL1.

External register MIDR_EL1 is architecturally mapped to AArch32 System register MIDR.

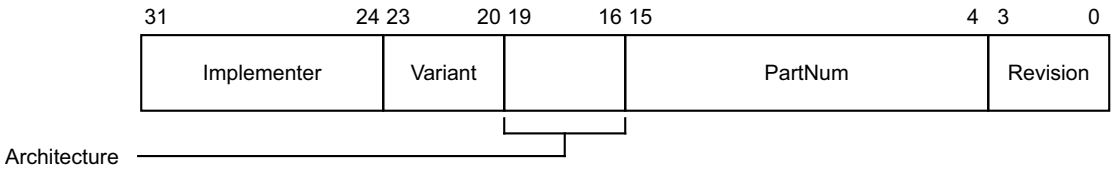
MIDR_EL1 is in the Debug power domain.

Attributes

MIDR_EL1 is a 32-bit register.

Field descriptions

The MIDR_EL1 bit assignments are:



Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by ARM. Assigned codes include the following:

Hex representation	ASCII representation	Implementer
0x41	A	ARM Limited
0x42	B	Broadcom Corporation
0x43	C	Cavium Inc.
0x44	D	Digital Equipment Corporation
0x49	I	Infineon Technologies AG
0x4D	M	Motorola or Freescale Semiconductor Inc.
0x4E	N	NVIDIA Corporation
0x50	P	Applied Micro Circuits Corporation

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Hex representation	ASCII representation	Implementer
0x51	Q	Qualcomm Inc.
0x56	V	Marvell International Ltd.
0x69	i	Intel Corporation

ARM can assign codes that are not published in this manual. All values not assigned by ARM are reserved and must not be used.

Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

Architecture, bits [19:16]

The permitted values of this field are:

0001 ARMv4

0010 ARMv4T

0011 ARMv5 (obsolete)

0100 ARMv5T

0101 ARMv5TE

0110 ARMv5TEJ

0111 ARMv6

1111 Architectural features are individually identified in the ID_* registers, see *Identification registers, functional group* on page G4-4048.

All other values are reserved.

PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

Accessing the MIDR_EL1:

MIDR_EL1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD00

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.2.46 OSLAR_EL1, OS Lock Access Register

The OSLAR_EL1 characteristics are:

Purpose

Used to lock or unlock the OS lock.

Usage constraints

This register is accessible as follows:

Off	DLK	SLK	Default
Error	Error	WI	WO

Configurations

External register OSLAR_EL1 is architecturally mapped to AArch64 System register OSLAR_EL1.

External register OSLAR_EL1 is architecturally mapped to AArch32 System register DBGOSLAR.

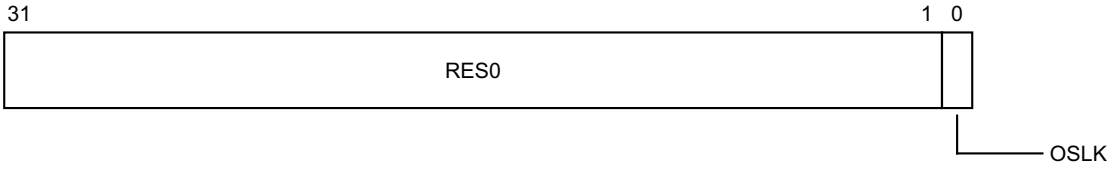
OSLAR_EL1 is in the Core power domain.

Attributes

OSLAR_EL1 is a 32-bit register.

Field descriptions

The OSLAR_EL1 bit assignments are:



Bits [31:1]

Reserved, RES0.

OSLK, bit [0]

On writes to OSLAR_EL1, bit[0] is copied to the OS lock.

Use EDPRSR.OSLK to check the current status of the lock.

Accessing the OSLAR_EL1:

OSLAR_EL1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x300

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3 Cross-Trigger Interface registers

This section lists the Cross-Trigger Interface registers.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.1 ASICCTL, CTI External Multiplexer Control register

The ASICCTL characteristics are:

Purpose

Provides a control for external multiplexing of additional triggers into the CTI.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RW

Configurations

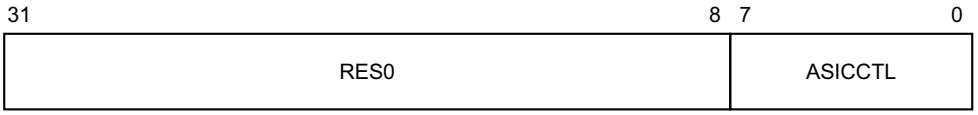
ASICCTL is in the Debug power domain.

Attributes

ASICCTL is a 32-bit register.

Field descriptions

The ASICCTL bit assignments are:



Bits [31:8]

Reserved, RES0.

ASICCTL, bits [7:0]

IMPLEMENTATION DEFINED ASIC control. Controls the external multiplexing of any additional triggers into the CTI.

Note

The architecturally-defined triggers must not be multiplexed.

If an implementation supports external multiplexing of additional trigger signals then CTIDEVID.EXTMUXNUM must indicate the number of multiplexed signals on each trigger.

If CTIDEVID.EXTMUXNUM is zero, this field is RAZ.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, the reset value of this field is architecturally UNKNOWN.

Accessing the ASICCTL:

ASICCTL can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	0x144

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.2 CTIAPPCLEAR, CTI Application Trigger Clear register

The CTIAPPCLEAR characteristics are:

Purpose

Clears bits of the Application Trigger register.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	WO

Configurations

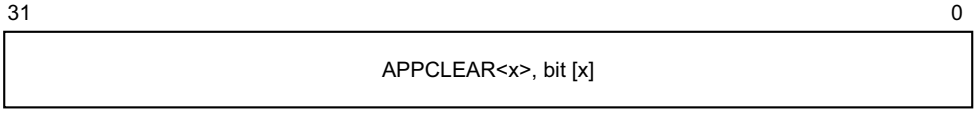
CTIAPPCLEAR is in the Debug power domain.

Attributes

CTIAPPCLEAR is a 32-bit register.

Field descriptions

The CTIAPPCLEAR bit assignments are:



APPCLEAR<x>, bit [x], for x = 0 to 31

Application trigger <x> disable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Writing to this bit has the following effect:

`0` No effect.

`1` Clear corresponding bit in CTIAPPTRIG to 0 and clear the corresponding channel event.

If the ECT does not support multicycle channel events, use of CTIAPPCLEAR is deprecated and the debugger must only use CTIAPPPULSE.

Accessing the CTIAPPCLEAR:

CTIAPPCLEAR can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x018`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.3 CTIAPPPULSE, CTI Application Pulse register

The CTIAPPPULSE characteristics are:

Purpose

Causes event pulses to be generated on ECT channels.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	WO

Configurations

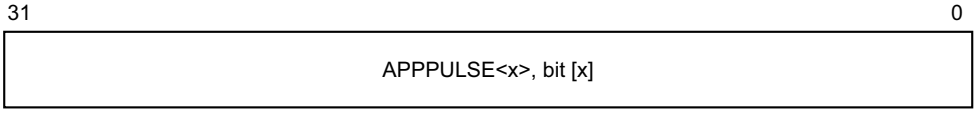
CTIAPPPULSE is in the Debug power domain.

Attributes

CTIAPPPULSE is a 32-bit register.

Field descriptions

The CTIAPPPULSE bit assignments are:



APPPULSE<x>, bit [x], for x = 0 to 31

Generate event pulse on ECT channel <x>.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Writing to this bit has the following effect:

`0` No effect.

`1` Channel <x> event pulse generated for one clock period.

Accessing the CTIAPPPULSE:

CTIAPPPULSE can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x01C`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.4 CTIAPPSET, CTI Application Trigger Set register

The CTIAPPSET characteristics are:

Purpose

Sets bits of the Application Trigger register.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RW

Configurations

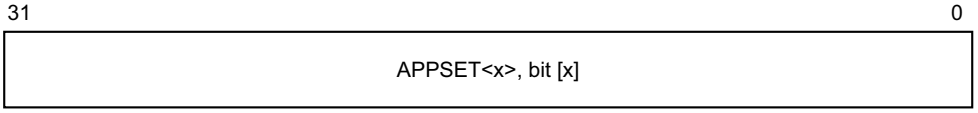
CTIAPPSET is in the Debug power domain.

Attributes

CTIAPPSET is a 32-bit register.

Field descriptions

The CTIAPPSET bit assignments are:



APPSET<x>, bit [x], for x = 0 to 31

Application trigger <x> enable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

`0` Reading this means the application trigger is inactive. Writing this has no effect.

`1` Reading this means the application trigger is active. Writing this sets the corresponding bit in CTIAPPTRIG to 1 and generates a channel event.

If the ECT does not support multicycle channel events, use of CTIAPPSET is deprecated and the debugger must only use CTIAPPPULSE.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the CTIAPPSET:

CTIAPPSET can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x014`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.5 CTIAUTHSTATUS, CTI Authentication Status register

The CTIAUTHSTATUS characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for CTI.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIAUTHSTATUS is in the Debug power domain.

This register is OPTIONAL, and is required for CoreSight compliance. ARM recommends that this register is implemented.

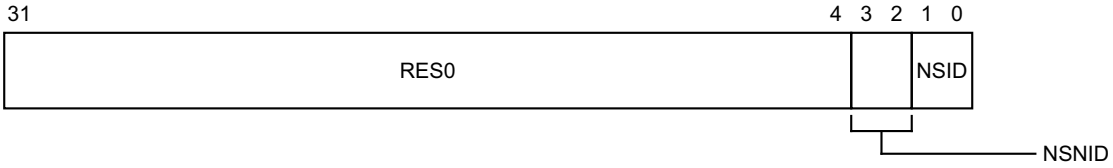
CTIAUTHSTATUS.{SNID,SID} are RAZ, because the CTI does not itself provide Secure authentication.

Attributes

CTIAUTHSTATUS is a 32-bit register.

Field descriptions

The CTIAUTHSTATUS bit assignments are:



Bits [31:4]

Reserved, RES0.

NSNID, bits [3:2]

If EL3 is not implemented and the implemented Security state is Secure state, holds the same value as DBGAUTHSTATUS_EL1.SNID.

Otherwise, holds the same value as DBGAUTHSTATUS_EL1.NSNID.

NSID, bits [1:0]

If EL3 is not implemented and the implemented Security state is Secure state, holds the same value as DBGAUTHSTATUS_EL1.SID.

Otherwise, holds the same value as DBGAUTHSTATUS_EL1.NSID.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the CTIAUTHSTATUS:

CTIAUTHSTATUS can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFB8

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.6 CTICHINSTATUS, CTI Channel In Status register

The CTICHINSTATUS characteristics are:

Purpose

Provides the raw status of the ECT channel inputs to the CTI.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

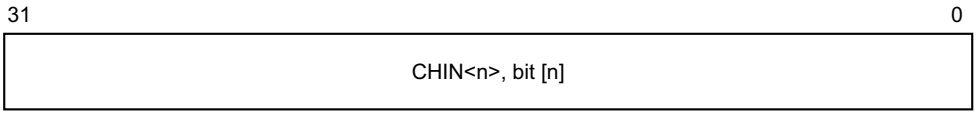
CTICHINSTATUS is in the Debug power domain.

Attributes

CTICHINSTATUS is a 32-bit register.

Field descriptions

The CTICHINSTATUS bit assignments are:



CHIN<n>, bit [n], for n = 0 to 31

Input channel <n> status.

Bits [31:N] are RAZ. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

`0` Input channel <n> is inactive.

`1` Input channel <n> is active.

Accessing the CTICHINSTATUS:

CTICHINSTATUS can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x138`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.7 CTICHOUTSTATUS, CTI Channel Out Status register

The CTICHOUTSTATUS characteristics are:

Purpose

Provides the status of the ECT channel outputs from the CTI.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

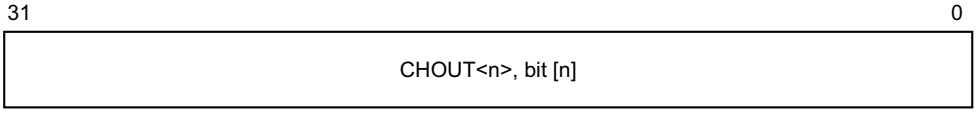
CTICHOUTSTATUS is in the Debug power domain.

Attributes

CTICHOUTSTATUS is a 32-bit register.

Field descriptions

The CTICHOUTSTATUS bit assignments are:



CHOUT<n>, bit [n], for n = 0 to 31

Output channel <n> status.

Bits [31:N] are RAZ. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

`0` Output channel <n> is inactive.

`1` Output channel <n> is active.

Accessing the CTICHOUTSTATUS:

CTICHOUTSTATUS can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x13C`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.8 CTICIDR0, CTI Component Identification Register 0

The CTICIDR0 characteristics are:

Purpose

Provides information to identify a CTI component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTICIDR0 is in the Debug power domain.

CTICIDR0 is optional to implement in the external register interface.

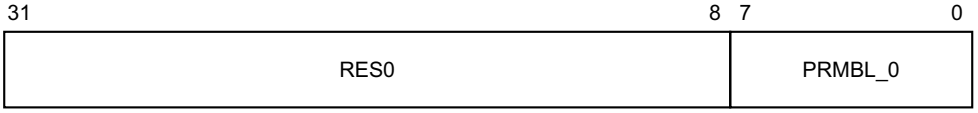
This register is required for CoreSight compliance.

Attributes

CTICIDR0 is a 32-bit register.

Field descriptions

The CTICIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_0, bits [7:0]

Preamble. Must read as `0x0D`.

Accessing the CTICIDR0:

CTICIDR0 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFF0`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.9 CTICIDR1, CTI Component Identification Register 1

The CTICIDR1 characteristics are:

Purpose

Provides information to identify a CTI component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTICIDR1 is in the Debug power domain.

CTICIDR1 is optional to implement in the external register interface.

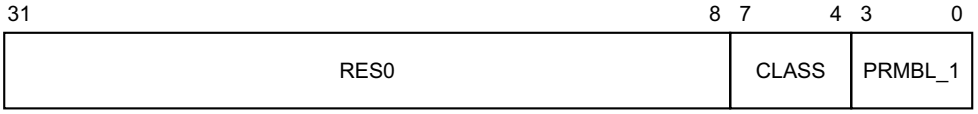
This register is required for CoreSight compliance.

Attributes

CTICIDR1 is a 32-bit register.

Field descriptions

The CTICIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

CLASS, bits [7:4]

Component class. Reads as `0x9`, debug component.

PRMBL_1, bits [3:0]

Preamble. RAZ.

Accessing the CTICIDR1:

CTICIDR1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFF4`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.10 CTICIDR2, CTI Component Identification Register 2

The CTICIDR2 characteristics are:

Purpose

Provides information to identify a CTI component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTICIDR2 is in the Debug power domain.

CTICIDR2 is optional to implement in the external register interface.

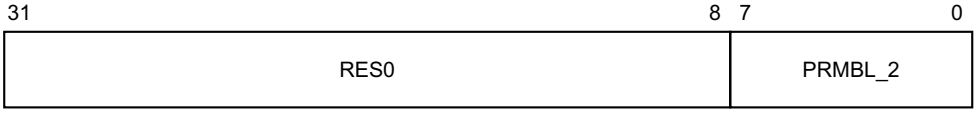
This register is required for CoreSight compliance.

Attributes

CTICIDR2 is a 32-bit register.

Field descriptions

The CTICIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

Preamble. Must read as `0x05`.

Accessing the CTICIDR2:

CTICIDR2 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFF8`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.11 CTICIDR3, CTI Component Identification Register 3

The CTICIDR3 characteristics are:

Purpose

Provides information to identify a CTI component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTICIDR3 is in the Debug power domain.

CTICIDR3 is optional to implement in the external register interface.

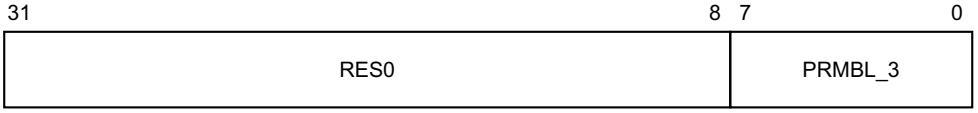
This register is required for CoreSight compliance.

Attributes

CTICIDR3 is a 32-bit register.

Field descriptions

The CTICIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_3, bits [7:0]

Preamble. Must read as `0xB1`.

Accessing the CTICIDR3:

CTICIDR3 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFFC`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.12 CTICLAIMCLR, CTI Claim Tag Clear register

The CTICLAIMCLR characteristics are:

Purpose

Used by software to read the values of the CLAIM bits, and to clear these bits to 0.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RW

Configurations

CTICLAIMCLR is in the Debug power domain.

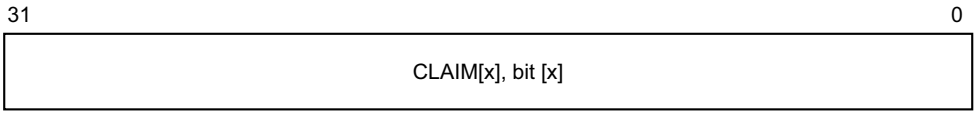
CTICLAIMCLR is optional to implement in the external register interface.

Attributes

CTICLAIMCLR is a 32-bit register.

Field descriptions

The CTICLAIMCLR bit assignments are:



CLAIM[x], bit [x], for x = 0 to 31

Clear CLAIM tag. If x is greater than or equal to the IMPLEMENTATION DEFINED number of CLAIM tags, this bit is RAZ/SBZ. Software can rely on these bits reading as zero, and must use a Should-Be-Zero policy on writes. Implementations must ignore writes.

Otherwise, reads return the value of CLAIM[x] and the behavior on writes is:

`0` No action.

`1` Indirectly clear CLAIM[x] to 0.

A single write to CTICLAIMCLR can clear multiple tags to 0.

Accessing the CTICLAIMCLR:

CTICLAIMCLR can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFA4`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.13 CTICLAIMSET, CTI Claim Tag Set register

The CTICLAIMSET characteristics are:

Purpose

Used by software to set CLAIM bits to 1.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RW

Configurations

CTICLAIMSET is in the Debug power domain.

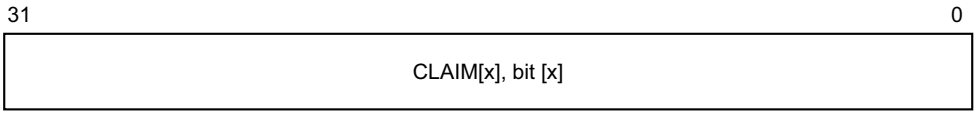
CTICLAIMSET is optional to implement in the external register interface.

Attributes

CTICLAIMSET is a 32-bit register.

Field descriptions

The CTICLAIMSET bit assignments are:



CLAIM[x], bit [x], for x = 0 to 31

CLAIM tag set bit. If x is greater than or equal to the IMPLEMENTATION DEFINED number of CLAIM tags, this bit is RAZ/SBZ. Software can rely on these bits reading as zero, and must use a Should-Be-Zero policy on writes. Implementations must ignore writes.

Otherwise, the bit is RAO and the behavior on writes is:

`0` No action.

`1` Indirectly set CLAIM[x] tag to 1.

A single write to CTICLAIMSET can set multiple tags to 1.

Accessing the CTICLAIMSET:

CTICLAIMSET can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFA0`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.14 CTICONTROL, CTI Control register

The CTICONTROL characteristics are:

Purpose

Controls whether the CTI is enabled.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RW

Configurations

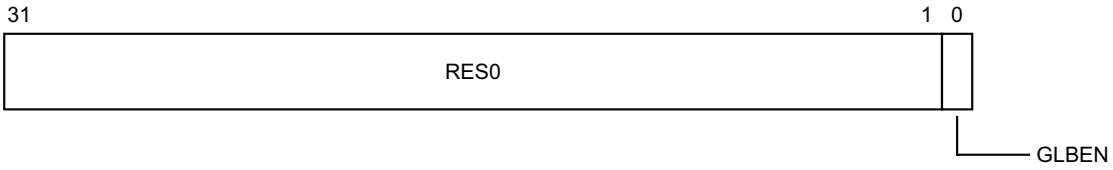
CTICONTROL is in the Debug power domain.

Attributes

CTICONTROL is a 32-bit register.

Field descriptions

The CTICONTROL bit assignments are:



Bits [31:1]

Reserved, RES0.

GLBEN, bit [0]

Enables or disables the CTI mapping functions. Possible values of this field are:

`0` CTI mapping functions disabled.

`1` CTI mapping functions enabled.

When the mapping functions are disabled, no new events are signaled on either output triggers or output channels. If a previously asserted output trigger has not been acknowledged, it remains asserted after the mapping functions are disabled. All output triggers are disabled by CTI reset.

When this register has an architecturally-defined reset value, this field resets to `0`.

Accessing the CTICONTROL:

CTICONTROL can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x000`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.15 CTIDEVAFF0, CTI Device Affinity register 0

The CTIDEVAFF0 characteristics are:

Purpose

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the CTI component relates to.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIDEVAFF0 is in the Debug power domain.

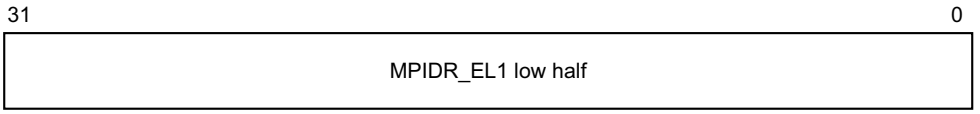
CTIDEVAFF0 is optional to implement in the external register interface.

Attributes

CTIDEVAFF0 is a 32-bit register.

Field descriptions

The CTIDEVAFF0 bit assignments are:



Bits [31:0]

MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented Exception level.

Accessing the CTIDEVAFF0:

CTIDEVAFF0 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFA8

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.16 CTIDEVAFF1, CTI Device Affinity register 1

The CTIDEVAFF1 characteristics are:

Purpose

Copy of the high half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the CTI component relates to.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIDEVAFF1 is in the Debug power domain.

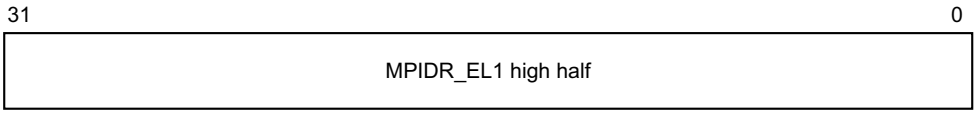
CTIDEVAFF1 is optional to implement in the external register interface.

Attributes

CTIDEVAFF1 is a 32-bit register.

Field descriptions

The CTIDEVAFF1 bit assignments are:



Bits [31:0]

MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented Exception level.

Accessing the CTIDEVAFF1:

CTIDEVAFF1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFAC

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.17 CTIDEVARCH, CTI Device Architecture register

The CTIDEVARCH characteristics are:

Purpose

Identifies the programmers' model architecture of the CTI component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIDEVARCH is in the Debug power domain.

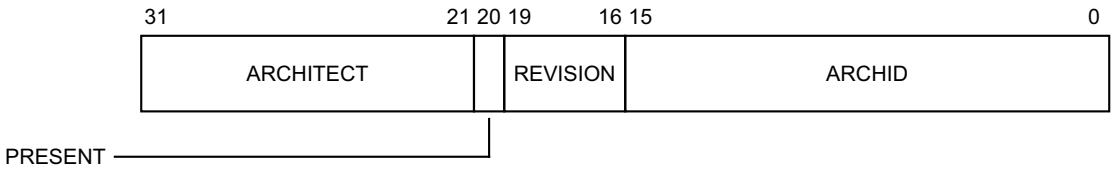
CTIDEVARCH is optional to implement in the external register interface.

Attributes

CTIDEVARCH is a 32-bit register.

Field descriptions

The CTIDEVARCH bit assignments are:



ARCHITECT, bits [31:21]

Defines the architecture of the component. For CTI, this is ARM Limited.

Bits [31:28] are the JEP 106 continuation code, `0x4`.

Bits [27:21] are the JEP 106 ID code, `0x3B`.

PRESENT, bit [20]

When set to 1, indicates that the DEVARCH is present.

This field is 1 in ARMv8.

REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by ARM this is the minor revision.

For CTI, the revision defined by ARMv8 is `0x0`.

All other values are reserved.

ARCHID, bits [15:0]

Defines this part to be an ARMv8 debug component. For architectures defined by ARM this is further subdivided.

For CTI:

- Bits [15:12] are the architecture version, `0x1`.
- Bits [11:0] are the architecture part number, `0xA14`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

This corresponds to CTI architecture version CTIv2.

Accessing the CTIDEVARCH:

CTIDEVARCH can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFBC

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.18 CTIDEVID, CTI Device ID register 0

The CTIDEVID characteristics are:

Purpose

Describes the CTI component to the debugger.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

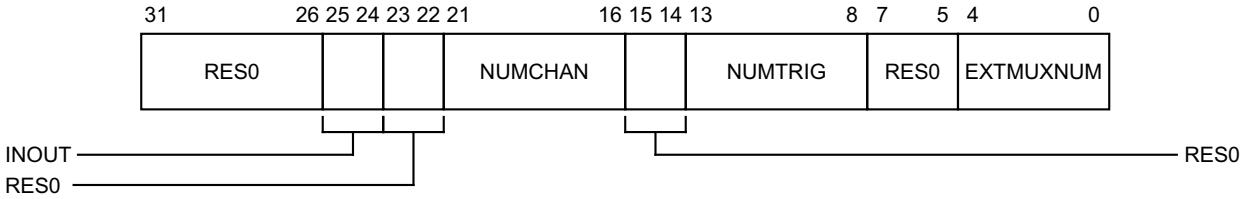
CTIDEVID is in the Debug power domain.

Attributes

CTIDEVID is a 32-bit register.

Field descriptions

The CTIDEVID bit assignments are:



Bits [31:26]

Reserved, RES0.

INOUT, bits [25:24]

Input/output options. Indicates presence of the input gate. If the CTM is not implemented, this field is RAZ.

`00` CTIGATE does not mask propagation of input events from external channels.

`01` CTIGATE masks propagation of input events from external channels.

All other values are reserved.

Bits [23:22]

Reserved, RES0.

NUMCHAN, bits [21:16]

Number of ECT channels implemented. IMPLEMENTATION DEFINED. For ARMv8, valid values are:

`000011` 3 channels (0..2) implemented.

`000100` 4 channels (0..3) implemented.

`000101` 5 channels (0..4) implemented.

`000110` 6 channels (0..5) implemented.

and so on up to `100000`, 32 channels (0..31) implemented.

All other values are reserved.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Bits [15:14]

Reserved, RES0.

NUMTRIG, bits [13:8]

Number of triggers implemented. IMPLEMENTATION DEFINED. This is one more than the index of the largest trigger, rather than the actual number of triggers.

For ARMv8, valid values are:

`000011` Up to 3 triggers (0..2) implemented.

`001000` Up to 8 triggers (0..7) implemented.

`001001` Up to 9 triggers (0..8) implemented.

`001010` Up to 10 triggers (0..9) implemented.

and so on up to `100000`, 32 triggers (0..31) implemented.

All other values are reserved. If the implementation includes an ARM trace macrocell, this field must be at least `001000`. There is no guarantee that any of the implemented triggers, including the highest numbered, are connected to any components.

Bits [7:5]

Reserved, RES0.

EXTMUXNUM, bits [4:0]

Number of multiplexors available on triggers. This value is used in conjunction with External Control register, ASICCTL.

Accessing the CTIDEVID:

CTIDEVID can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFC8`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.19 CTIDEVID1, CTI Device ID register 1

The CTIDEVID1 characteristics are:

Purpose

Reserved for future information about the CTI component to the debugger.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

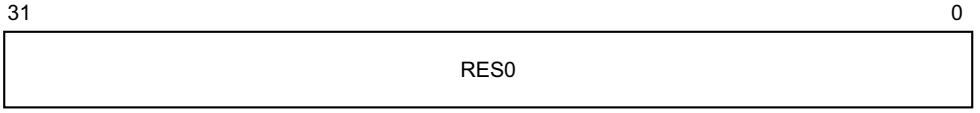
CTIDEVID1 is in the Debug power domain.

Attributes

CTIDEVID1 is a 32-bit register.

Field descriptions

The CTIDEVID1 bit assignments are:



Bits [31:0]

Reserved, RES0.

Accessing the CTIDEVID1:

CTIDEVID1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFC4

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.20 CTIDEVID2, CTI Device ID register 2

The CTIDEVID2 characteristics are:

Purpose

Reserved for future information about the CTI component to the debugger.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

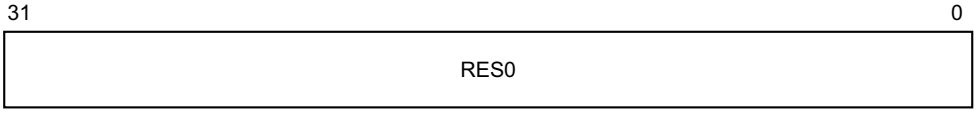
CTIDEVID2 is in the Debug power domain.

Attributes

CTIDEVID2 is a 32-bit register.

Field descriptions

The CTIDEVID2 bit assignments are:



Bits [31:0]

Reserved, RES0.

Accessing the CTIDEVID2:

CTIDEVID2 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFC0

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.21 CTIDEVTYPE, CTI Device Type register

The CTIDEVTYPE characteristics are:

Purpose

Indicates to a debugger that this component is part of a PEs cross-trigger interface.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIDEVTYPE is in the Debug power domain.

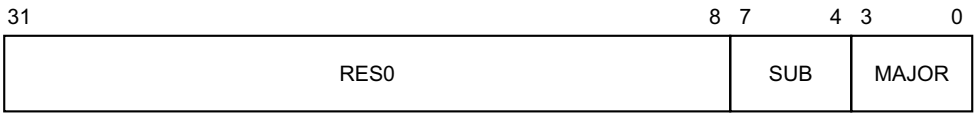
CTIDEVTYPE is optional to implement in the external register interface.

Attributes

CTIDEVTYPE is a 32-bit register.

Field descriptions

The CTIDEVTYPE bit assignments are:



Bits [31:8]

Reserved, RES0.

SUB, bits [7:4]

Subtype. Must read as `0x1` to indicate this is a component within a PE.

MAJOR, bits [3:0]

Major type. Must read as `0x4` to indicate this is a cross-trigger component.

Accessing the CTIDEVTYPE:

CTIDEVTYPE can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFCC`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.22 CTIGATE, CTI Channel Gate Enable register

The CTIGATE characteristics are:

Purpose

Determines whether events on channels propagate through the CTM to other ECT components, or from the CTM into the CTI.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RW

Configurations

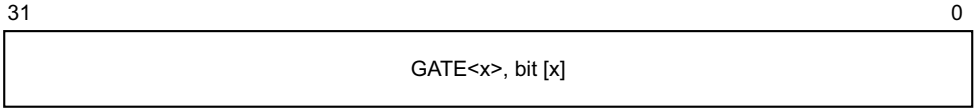
CTIGATE is in the Debug power domain.

Attributes

CTIGATE is a 32-bit register.

Field descriptions

The CTIGATE bit assignments are:



GATE<x>, bit [x], for x = 0 to 31

Channel <x> gate enable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

`0` Disable output and, if CTIDEVID.INOUT == `0b01`, input channel <x> propagation.

`1` Enable output and, if CTIDEVID.INOUT == `0b01`, input channel <x> propagation.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the CTIGATE:

CTIGATE can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x140`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.23 CTIINEN<n>, CTI Input Trigger to Output Channel Enable registers, n = 0 - 31

The CTIINEN<n> characteristics are:

Purpose

Enables the signaling of an event on output channels when input trigger event n is received by the CTI.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RW

Configurations

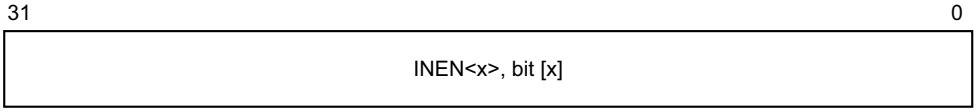
CTIINEN<n> is in the Debug power domain.

Attributes

CTIINEN<n> is a 32-bit register.

Field descriptions

The CTIINEN<n> bit assignments are:



INEN<x>, bit [x], for x = 0 to 31

Input trigger <n> to output channel <x> enable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

`0` Input trigger <n> will not generate an event on output channel <x>.

`1` Input trigger <n> will generate an event on output channel <x>.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the CTIINEN<n>:

CTIINEN<n> can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x020` + 4n

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.24 CTIINTACK, CTI Output Trigger Acknowledge register

The CTIINTACK characteristics are:

Purpose

Can be used to create soft acknowledges for output triggers.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	WO

A debugger must read CTITRIGOUTSTATUS to confirm that the output trigger has been acknowledged before generating any event that must be ordered after the write to CTIINTACK.

Configurations

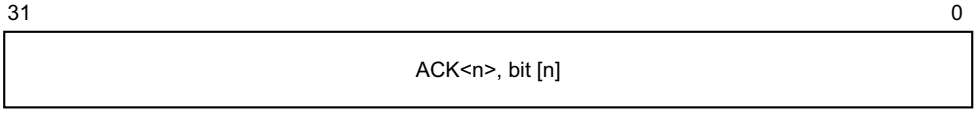
CTIINTACK is in the Debug power domain.

Attributes

CTIINTACK is a 32-bit register.

Field descriptions

The CTIINTACK bit assignments are:



ACK<n>, bit [n], for n = 0 to 31

Acknowledge for output trigger <n>.

Bits [31:N] are RAZ/WI. N is the number of CTI triggers implemented as defined by the CTIDEVID.NUMTRIG field.

If any of the following is true, writes to ACK<n> are ignored:

- n >= CTIDEVID.NUMTRIG, the number of implemented triggers.
- Output trigger n is not active.
- The channel mapping function output, as controlled by CTIOUTEN<n>, is still active.

Otherwise, if any of the following are true, it is IMPLEMENTATION DEFINED whether writes to ACK<n> are ignored:

- Output trigger n is not implemented.
- Output trigger n is not connected.
- Output trigger n is self-acknowledging and does not require software acknowledge.

Otherwise, the behavior on writes to ACK<n> is as follows:

`0` No effect

`1` Deactivate the trigger.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the CTIINTACK:

CTIINTACK can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	0x010

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.25 CTIITCTRL, CTI Integration mode Control register

The CTIITCTRL characteristics are:

Purpose

Enables the CTI to switch from its default mode into integration mode, where test software can control directly the inputs and outputs of the PE, for integration testing or topology detection.

Usage constraints

This register is accessible as follows:

Default
RW

Configurations

CTIITCTRL is in the Debug power domain.

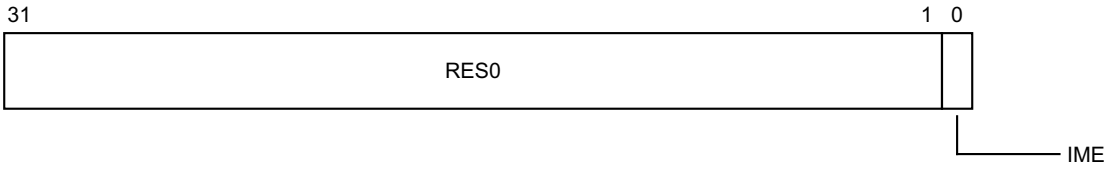
CTIITCTRL is optional to implement in the external register interface.

Attributes

CTIITCTRL is a 32-bit register.

Field descriptions

The CTIITCTRL bit assignments are:



Bits [31:1]

Reserved, RES0.

IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

`0` Normal operation.

`1` Integration mode enabled.

When this register has an architecturally-defined reset value, this field resets to `0`.

Accessing the CTIITCTRL:

CTIITCTRL can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xF00`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.26 CTILAR, CTI Lock Access Register

The CTILAR characteristics are:

Purpose

Allows or disallows access to the CTI registers through a memory-mapped interface.

Usage constraints

This register is accessible as follows:

Default
WO

Configurations

CTILAR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software lock can be implemented as part of CoreSight compliance.

CTILAR ignores writes if the Software lock is not implemented and ignores writes for other accesses to the external debug interface.

The Software lock provides a lock to prevent memory-mapped writes to the Cross-Trigger Interface registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Cross-Trigger Interface registers. It does not, and cannot, prevent all accidental or malicious damage.

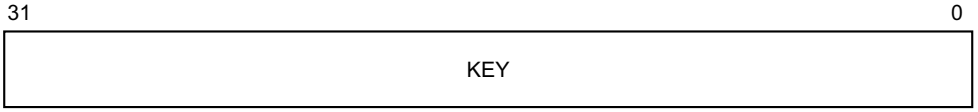
Software uses CTILAR to set or clear the lock, and CTILSR to check the current status of the lock.

Attributes

CTILAR is a 32-bit register.

Field descriptions

The CTILAR bit assignments are:



KEY, bits [31:0]

Lock Access control. Writing the key value `0xC5ACCE55` to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

Accessing the CTILAR:

CTILAR can be accessed through the memory-mapped interface:

Component	Offset
CTI	`0xFB0`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.27 CTILSR, CTI Lock Status Register

The CTILSR characteristics are:

Purpose

Indicates the current status of the software lock for CTI registers.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

CTILSR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software lock can be implemented as part of CoreSight compliance.

CTILSR is RAZ if the Software lock is not implemented and is RAZ for other accesses to the external debug interface.

The Software lock provides a lock to prevent memory-mapped writes to the Cross-Trigger Interface registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Cross-Trigger Interface registers. It does not, and cannot, prevent all accidental or malicious damage.

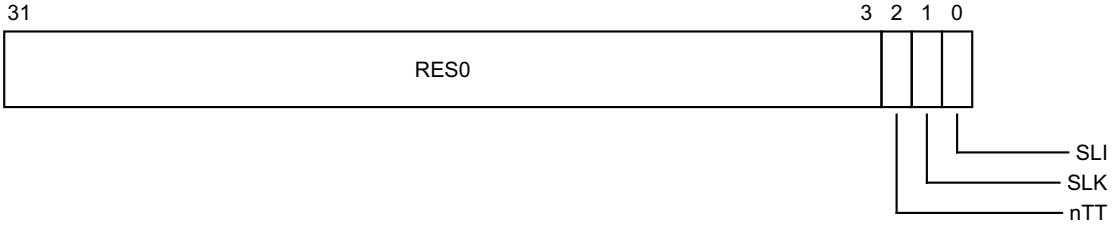
Software uses CTILAR to set or clear the lock, and CTILSR to check the current status of the lock.

Attributes

CTILSR is a 32-bit register.

Field descriptions

The CTILSR bit assignments are:



Bits [31:3]

Reserved, RES0.

nTT, bit [2]

Not thirty-two bit access required. RAZ.

SLK, bit [1]

Software lock status for this component. For an access to LSR that is not a memory-mapped access, or when the software lock is not implemented, this field is RES0.

For memory-mapped accesses when the software lock is implemented, possible values of this field are:

`0` Lock clear. Writes are permitted to this component's registers.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

`1` Lock set. Writes to this component's registers are ignored, and reads have no side effects.

When this register has an architecturally-defined reset value, this field resets to `1`.

SLI, bit [0]

Software lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are:

`0` Software lock not implemented or not memory-mapped access.

`1` Software lock implemented and memory-mapped access.

Accessing the CTILSR:

CTILSR can be accessed through the memory-mapped interface:

Component	Offset
CTI	`0xFB4`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.28 CTIOUTEN<n>, CTI Input Channel to Output Trigger Enable registers, n = 0 - 31

The CTIOUTEN<n> characteristics are:

Purpose

Defines which input channels generate output trigger n.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RW

Configurations

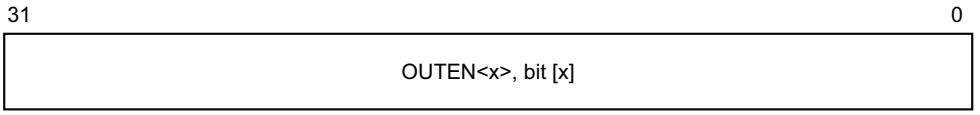
CTIOUTEN<n> is in the Debug power domain.

Attributes

CTIOUTEN<n> is a 32-bit register.

Field descriptions

The CTIOUTEN<n> bit assignments are:



OUTEN<x>, bit [x], for x = 0 to 31

Input channel <x> to output trigger <n> enable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

`0` An event on input channel <x> will not cause output trigger <n> to be asserted.

`1` An event on input channel <x> will cause output trigger <n> to be asserted.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the CTIOUTEN<n>:

CTIOUTEN<n> can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x0A0` + 4n

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.29 CTIPIDR0, CTI Peripheral Identification Register 0

The CTIPIDR0 characteristics are:

Purpose

Provides information to identify a CTI component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIPIDR0 is in the Debug power domain.

CTIPIDR0 is optional to implement in the external register interface.

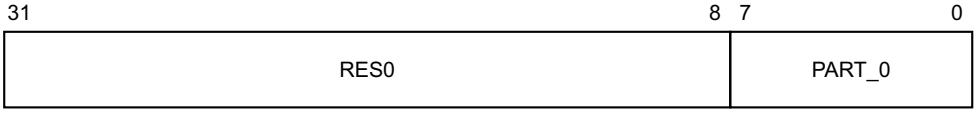
This register is required for CoreSight compliance.

Attributes

CTIPIDR0 is a 32-bit register.

Field descriptions

The CTIPIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PART_0, bits [7:0]

Part number, least significant byte.

Accessing the CTIPIDR0:

CTIPIDR0 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFE0

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.30 CTIPIDR1, CTI Peripheral Identification Register 1

The CTIPIDR1 characteristics are:

Purpose

Provides information to identify a CTI component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIPIDR1 is in the Debug power domain.

CTIPIDR1 is optional to implement in the external register interface.

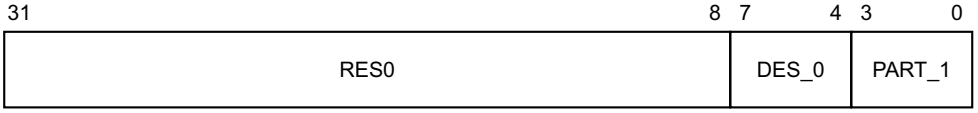
This register is required for CoreSight compliance.

Attributes

CTIPIDR1 is a 32-bit register.

Field descriptions

The CTIPIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

DES_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is `0b1011`.

PART_1, bits [3:0]

Part number, most significant nibble.

Accessing the CTIPIDR1:

CTIPIDR1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFE4`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.31 CTIPIDR2, CTI Peripheral Identification Register 2

The CTIPIDR2 characteristics are:

Purpose

Provides information to identify a CTI component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIPIDR2 is in the Debug power domain.

CTIPIDR2 is optional to implement in the external register interface.

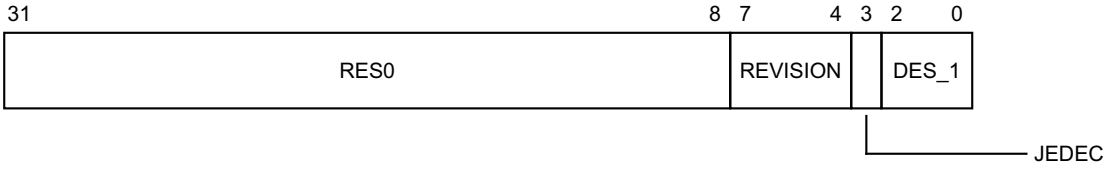
This register is required for CoreSight compliance.

Attributes

CTIPIDR2 is a 32-bit register.

Field descriptions

The CTIPIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

JEDEC, bit [3]

RAO. Indicates a JEP106 identity code is used.

DES_1, bits [2:0]

Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is `0b011`.

Accessing the CTIPIDR2:

CTIPIDR2 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFE8`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.32 CTIPIDR3, CTI Peripheral Identification Register 3

The CTIPIDR3 characteristics are:

Purpose

Provides information to identify a CTI component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIPIDR3 is in the Debug power domain.

CTIPIDR3 is optional to implement in the external register interface.

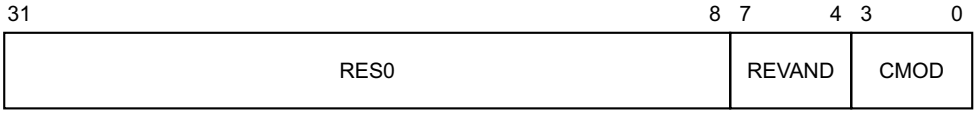
This register is required for CoreSight compliance.

Attributes

CTIPIDR3 is a 32-bit register.

Field descriptions

The CTIPIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVAND, bits [7:4]

Part minor revision. Parts using CTIPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.

CMOD, bits [3:0]

Customer modified. Indicates someone other than the Designer has modified the component.

Accessing the CTIPIDR3:

CTIPIDR3 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFEC

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.33 CTIPIDR4, CTI Peripheral Identification Register 4

The CTIPIDR4 characteristics are:

Purpose

Provides information to identify a CTI component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIPIDR4 is in the Debug power domain.

CTIPIDR4 is optional to implement in the external register interface.

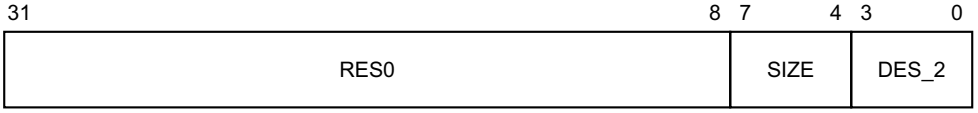
This register is required for CoreSight compliance.

Attributes

CTIPIDR4 is a 32-bit register.

Field descriptions

The CTIPIDR4 bit assignments are:



Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. RAZ. Log_2 of the number of 4KB pages from the start of the component to the end of the component ID registers.

DES_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is `0b0100`.

Accessing the CTIPIDR4:

CTIPIDR4 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFD0`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.34 CTITRIGINSTATUS, CTI Trigger In Status register

The CTITRIGINSTATUS characteristics are:

Purpose

Provides the status of the trigger inputs.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

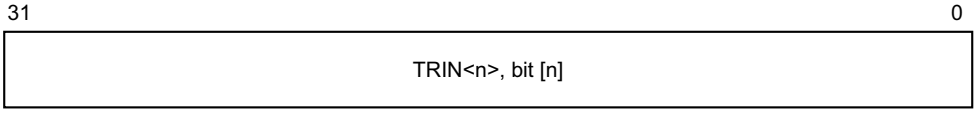
CTITRIGINSTATUS is in the Debug power domain.

Attributes

CTITRIGINSTATUS is a 32-bit register.

Field descriptions

The CTITRIGINSTATUS bit assignments are:



TRIN<n>, bit [n], for n = 0 to 31

Trigger input <n> status.

Bits [31:N] are RAZ. N is the number of CTI triggers implemented as defined by the CTIDEVID.NUMTRIG field.

Possible values of this bit are:

`0` Input trigger n is inactive.

`1` Input trigger n is active.

Not implemented and not-connected input triggers are always inactive.

Accessing the CTITRIGINSTATUS:

CTITRIGINSTATUS can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x130`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

H9.3.35 CTITRIGOUTSTATUS, CTI Trigger Out Status register

The CTITRIGOUTSTATUS characteristics are:

Purpose

Provides the raw status of the trigger outputs, after processing by any IMPLEMENTATION DEFINED trigger interface logic. For output triggers that are self-acknowledging, this is only meaningful if the CTI implements multicycle channel events.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

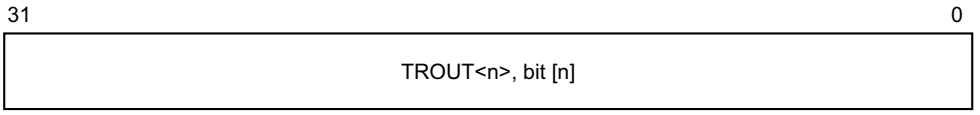
CTITRIGOUTSTATUS is in the Debug power domain.

Attributes

CTITRIGOUTSTATUS is a 32-bit register.

Field descriptions

The CTITRIGOUTSTATUS bit assignments are:



TROUT<n>, bit [n], for n = 0 to 31

Trigger output <n> status.

Bits [31:N] are RAZ, where N is the value of the CTIDEVID.NUMTRIG field.

If n < N, and output trigger <n> is implemented and connected, and either the trigger is not self-acknowledging or the CTI implements multicycle channel events, then permitted values for TROUT<n> are:

`0` Output trigger n is inactive.

`1` Output trigger n is active.

Otherwise when n < N it is IMPLEMENTATION DEFINED whether TROUT<n> behaves as described here or is RAZ.

Accessing the CTITRIGOUTSTATUS:

CTITRIGOUTSTATUS can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x134`

Part I

Memory-mapped Components of the ARMv8 Architecture

Chapter I1
System Level Implementation of the Generic Timer

This chapter defines the system level implementation of the Generic Timer. It contains the following sections:

- *About the Generic Timer specification* on page I1-4964.
- *Memory-mapped counter module* on page I1-4965.
- *Memory-mapped timer components* on page I1-4969.
- *Providing a complete set of counter and timer features* on page I1-4973.
- *Gray-count scheme for timer distribution scheme* on page I1-4975.

Note

- *Generic Timer memory-mapped register descriptions* on page I3-5038 describes the System level Generic Timer registers. These registers are memory-mapped.
- Chapter D6 *The Generic Timer in AArch64 state* gives a general description of the AArch64 state view of the Generic Timer, and describes the AArch64 System register interface to the Generic Timer.
- Chapter G5 *The Generic Timer in AArch32 state* gives a general description of the AArch32 state view of the Generic Timer, and describes the AArch32 System register interface to the Generic Timer.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I1.1 About the Generic Timer specification

Chapter D6 *The Generic Timer in AArch64 state* describes the ARM Generic Timer and its implementation as seen from AArch64 state. Chapter G5 *The Generic Timer in AArch32 state* describes the ARM Generic Timer and its implementation as seen from AArch32 state. These chapters include the definition of the low-latency System register interface to the Generic Timer. However, the ARM Generic Timer architecture requires the inclusion of a memory-mapped component, the memory-mapped counter module, to control the generation of the Count value used by the Generic Timers.

In addition, the Generic Timer architecture defines the architecture of an optional memory-mapped timer component. This gives a standardized way of providing timers for programmable system components other than PEs that implement the ARM architecture.

The full set of Generic Timer components on page D6-1791 summarizes these components as seen from AArch64 state, and *The full set of Generic Timer components* on page G5-4073 summarizes them as seen from AArch32 state. *The system level components of the Generic Timer* summarizes the system level components.

I1.1.1 Registers in the system level implementation of the Generic Timer

Registers that control components of the system level implementation of the Generic Timer are grouped into *frames*. This specification defines the registers in each frame, and their offsets within the frame. The system defines the position of each frame in the memory map. This means the base addresses for each frame is IMPLEMENTATION DEFINED.

Note

The final twelve words of the first or only 4KB block of a register memory frame is an ID block.

I1.1.2 The system level components of the Generic Timer

Each system level component has one or two register frames. The possible system level components are:

The memory-mapped counter module, required

This module controls the system counter. It has two frames:

- A control frame, CNTControlBase.
- A status frame, CNTReadBase.

Memory-mapped counter module on page I1-4965 describes this component.

The memory-mapped timer control module, required

The system level implementation of the Generic Timer can provide up to eight timers, and the memory-mapped timer control module identifies:

- Which timers are implemented.
- The features of each implemented timer.

This module has a single frame, CNTCTLBase.

The CNTCTLBase frame on page I1-4969 describes this frame.

Memory-mapped timers, optional

An implemented memory-mapped timer:

- Must provide a privileged view of the timer, in the CNTBase*N* frame.
- Optionally. provides an unprivileged view of the timer in the CNTEL0Base*N* frame.

N is the timer number, and the corresponding frame number, in the range 0-7.

The CNTBaseN and CNTEL0BaseN frames on page I1-4970 describes these frames.

I1.2 Memory-mapped counter module

The memory-mapped counter module provides top-level control of the system counter. The CNTControlBase frame holds the registers for the memory-mapped counter, and provides:

- A RW control register CNTCR, that provides:
  - An enable bit for the system counter.
  - An enable bit for Halt-on-Debug. When this is enabled, if the debug halt signal into the system counter is asserted, it halts the system counter. Otherwise, the system counter ignores the state of this halt signal. For more information about Halt-on-Debug, contact ARM.
  - A field that can be written to request a change to the update frequency of the system counter, with a corresponding change to the increment made at each update. This mechanism means that, for example, if the update frequency is halved, the increment at each update is doubled.

    For more information see *Control of counter operating frequency and increment* on page I1-4966.

  Writes to this register are rare. In a system that supports two Security states, this register is writable only by Secure writes.

- A RO status register, CNTSR, that provides:
  - A bit that indicates whether the system counter is halted because of an asserted Halt-on-Debug signal.
  - A field that indicates the current update frequency of the system counter. This field can be polled to determine when a requested change to the update frequency has been made.

- Two contiguous 32-bit RW registers that hold the current system counter value, CNTCV. If the system supports 64-bit atomic accesses, these two registers must be accessible by such accesses.

  The system counter must be disabled before writing to these registers, otherwise the effect of the write is UNPREDICTABLE.

  Writes to these registers are rare. In a system that supports two Security states, these registers are writable only by Secure writes.

- A table of one or more 32-bit entries, where:
  - The first entry defines the *base frequency* of the system counter. This is the maximum frequency at which the counter updates.
  - Each subsequent entry defines an alternative frequency of the system counter, that must be an exact divisor of the base frequency.

  A 32-bit zero entry immediately follows the last table entry.

  This table can be RO or RW. For more information, see *The frequency modes table* on page I1-4966.

In addition, the CNTReadBase frame includes a read-only copy of the system counter value, CNTCV, as two contiguous 32-bit RO registers. If the system supports 64-bit atomic accesses, these two registers must be accessible by such accesses.

Counter module control and status register summary on page I1-4967 describes CNTReadBase and CNTControlBase memory maps, and the registers in each frame.

Non-Confidential - Beta

I1.2.1 Control of counter operating frequency and increment

The system counter has a fixed *base frequency*, and must maintain the required counter accuracy, meaning ARM recommends that it does not gain or lose more than ten seconds in a 24-hour period, see *The system counter* on page D6-1792. However, the counter can increment at a lower frequency than the base frequency, using a correspondingly larger increment. For example, it can increment by four at a quarter of the base frequency. Any lower-frequency operation, and any switching between operating frequencies, must not reduce the accuracy of the counter.

Control of the system counter frequency and increment is provided only through the memory-mapped counter module. The following sections describe this control:

- *The frequency modes table*.
- *Changing the system counter and increment*.

The frequency modes table

The frequency modes table starts at offset `0x20` in the CNTControlBase frame.

Table entries are 32-bits, and each entry specifies a system counter update frequency, in Hz.

The first entry in the table specifies the base frequency of the system counter.

When the system timer is operating at a lower frequency than the base frequency, the increment applied at each counter update is given by:

increment = (base_frequency) / (selected_frequency)

A 32-bit word of zero value marks the end of the table. That is, the word of memory immediately after the last entry in the table must be zero.

The only required entry in the table is the entry for the base frequency.

Typically, the frequency modes table is in RO memory. However, a system implementation might use RW memory for the table, and initialize the table entries as part of its startup sequence. Therefore, the CNTControlBase memory map shows the table region as RO or RW.

ARM strongly recommends that the frequency modes table is not updated once the system is running.

The architecture can support up to 1004 entries in the frequency modes table, and the maximum number of entries is IMPLEMENTATION DEFINED, up to this limit.

Note

ARM considers it likely that implementations will require significantly fewer entries than the architectural limit.

Changing the system counter and increment

The value of the CNTCR.FREQ field specifies which frequency modes table entry specifies the system counter update frequency.

Changing the value of CNTCR.FREQ requests a change to the system counter update frequency. To ensure the frequency change does not affect the overall accuracy of the counter, a change is made as follows:

- When changing from a higher frequency to a lower frequency, the counter:
  1. Continues running at the higher frequency until the count reaches an integer multiple of the required lower frequency.
  2. Switches to operating at the lower frequency.
- When changing from a lower frequency to a higher frequency, the counter:
  1. Waits until the end of the current lower-frequency cycle.
  2. Makes the counter increment required for operation at that lower frequency.
  3. Switches to operating at the higher frequency.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

When the frequency has changed, CNTSR is updated to indicate the new frequency. Therefore, a system component that is waiting for a frequency change can poll CNTSR to detect the change.

I1.2.2 Counter module control and status register summary

The Counter module control and status registers are memory-mapped registers in the following register memory *frames*:

- A control frame, with base address CNTControlBase.
- A status frame, with base address CNTReadBase.

Each of these register memory frames is at least 4KB in size, or is at least the size of the memory protection granule if this granule size is larger than 4KB. Similarly, each base address must be aligned to 4KB, or to the memory protection granule if that is larger than 4KB.

Note

- The memory protection granule is either 4KB, 16KB or 64KB.
- Each frame of a memory-mapped Generic Timer takes the name of its base address.

In each register memory frame, the memory at offset `0xFD0-0xFFF` is reserved for twelve 32-bit IMPLEMENTATION DEFINED ID registers, see the CounterID<n> register descriptions for more information.

The counter is assumed to be little-endian.

In an implementation that supports Secure and Non-secure memory spaces, CNTControlBase is implemented only in the Secure memory space.

Table I1-1 shows the CNTControlBase control registers, in order of their offsets from the CNTControlBase base address. *Generic Timer memory-mapped register descriptions* on page I3-5038 describes each of these registers.

Table I1-1 CNTControlBase memory map

Offset	Name	Type	Description
`0x000`	CNTCR	RW	Counter Control Register.
`0x004`	CNTSR	RO	Counter Status Register.
`0x008`	CNTCV[31:0]	RW	Counter Count Value register.
`0x00C`	CNTCV[63:32]	RW	
`0x010-0x01C`	-	RES0	Reserved.
`0x020`	CNTFID0	RO or RW	Frequency modes table, and end marker. CNTFID0 is the base frequency, and each CNTFID*n* is an alternative frequency. For more information see *The frequency modes table* on page I1-4966.
`0x020+4`*n*	CNTFID*n*	RO or RW	
`(0x024+4`*n*`)-0x0BC`	-	RES0	Reserved.
`0x0C0-0x0FC`	-	IMPLEMENTATION DEFINED	Reserved for IMPLEMENTATION DEFINED registers.
`0x100-0xFCC`	-	RES0	Reserved.
`0xFD0-0xFFC`	CounterID<n>	RO	Counter ID registers 0-11.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Table I1-2 shows the CNTReadBase control registers, in order of their offsets from the CNTReadBase base address. *Generic Timer memory-mapped register descriptions* on page I3-5038 describes each of these registers.

Table I1-2 CNTReadBase memory map

Offset	Name	Type	Description
0x000	CNTCV[31:0]	RO	Counter Count Value register
0x004	CNTCV[63:32]	RO	
0x008-0xFCC	-	res0	Reserved
0xFD0-0xFFC	CounterID<n>	RO	Counter ID registers 0-11

I1.3 Memory-mapped timer components

This part of the ARM Generic Timer specification defines an optional memory-mapped timer component. This can be implemented as part of any programmable system component that does not incorporate a System register mapped ARM Generic Timer, to provide that system component with the timer functionality of an ARM Generic Timer.

The memory map consists of up to 8 timer *frames*. Each timer frame:

- Provides its own set of timers and associated interrupts.
- Is in its own memory protection region that is:
  - In its own memory protection region, with a system-defined size of 4KB, 16KB or 64KB.
  - At a start address that is aligned to 4KB.

  Note

  The start address 4KB alignment requirement applies regardless of the memory protection region size.

The base address of a frame is CNTBase*N*, where *N* numbers from 0 up to a maximum permitted value of 7.

For each implemented CNTBase*N* frame the system can optionally provide an unprivileged view of the frame, described as the EL0 view of the frame. The base address of this second view of the CNTBase*N* frame is CNTEL0Base*N*.

Note

In the naming of the registers associated with a CNTBase*N* or CNTEL0Base*N* frame, the value of *N* is represented as <n>, for example CNTACR<n>.

If a CNTEL0Base*N* frame is implemented:

- All registers visible in CNTBase*N* are visible, except for CNTVOFF and CNTEL0ACR.
- The offsets of all visible registers are the same as their offsets in the CNTBase*N* frame.

In addition to the implemented CNTBase*N* and CNTEL0Base*N* frames, the system must provide a single control frame at base address CNTCTLBase.

The memory protection region and alignment requirements for the CNTEL0Base*N* and CNTCTLBase frames are the same as the requirements for the CNTBase*N* frames.

The system defines the position of each frame in the memory map. This means the values of each of the CNTBase*N*, CNTEL0Base*N*, and CNTCTLBase base addresses is IMPLEMENTATION DEFINED.

The memory-mapped timers are assumed to be little-endian.

The following sections describe the implementation of a memory-mapped view of the counter and timer:

- *The CNTBaseN and CNTEL0BaseN frames* on page I1-4970.
- *The CNTCTLBase frame*.
- *Providing a complete set of counter and timer features* on page I1-4973.

I1.3.1 The CNTCTLBase frame

The CNTCTLBase frame contains:

- An identification register for the features of the memory-mapped counter and timer implementation.
- Access controls for each CNTBase*N* frame.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- A virtual offset register for frames that implement a virtual timer.

Table I1-3 shows the CNTCTLBase registers, in order of their offsets from the CNTCTLBase base address.

Note

. CNTFRQ and CNTVOFF registers are also implemented in a System register interface to the Generic Timer.

Generic Timer memory-mapped register descriptions on page I3-5038 describes each of these registers.

Table I1-3 CNTCTLBase memory map

Offset	Register	Type	Security[a]	Description
0x000	CNTFRQ[b]	RW	Secure	Counter Frequency register.
0x004	CNTNSAR	RW	Secure	Counter Non-Secure Access register.
0x008	CNTTIDR	RO	Both	Counter Timer ID register.
0x00C- 0x03F	-	res0	-	Reserved.
0x040+4*N*[c]	CNTACR<n>	RW	Configurable[d]	Counter Access Control register *N*.
0x060- 0x07F	-	res0	-	Reserved.
0x080+8*N*[c]	CNTVOFF<n>[31:0][b]	RW[e]	Configurable[d]	Virtual Offset register *N*. IMPLEMENTATION DEFINED whether this register is RW or RAZ. Optional in the CNTCTLBase memory map.
0x084+8*N*[c]	CNTVOFF<n>[63:32][b]	RW[e]		
0x0C0-0x0FC	-	UNK/SBZP	-	Reserved.
0x100-0x7FC	-	-	-	IMPLEMENTATION DEFINED.
0x800-0xFBC	-	UNK/SBZP	-	Reserved.
0xFC0-0xFCF	-	-	-	IMPLEMENTATION DEFINED.
0xFD0- 0xFFC	CounterID<n>	RO	Both	Counter ID registers 0-11.

a. Access security requirement in an implementation that supports two Security states. In an implementation that does not support multiple Security states all registers are accessible as shown in the *Type* column.
b. These registers are also defined in the System register interface to the Generic Timer, and therefore are also described in *Generic Timer registers* on page D7-2172 and *Generic Timer registers* on page G6-4654. The bit assignments of the registers are identical in the System register interface and in the memory-mapped system level interface.
c. Implemented for each value of *N* from 0 to 7 for which a CNTBase*N* frame is implemented.
d. The CNTNSAR determines the Non-secure accessibility of the CNTACR<n>s and the CNTVOFF<n>s in the CNTCTLBase frame. For more information, see the register descriptions.
e. Address is reserved, RAZ/WI if register not implemented.

All implementations of the Generic Timer include the virtual counter. Therefore, conceptually, all implementations include the CNTVOFF register that defines the virtual offset between the physical count and the virtual count. If a memory-mapped Generic Timer component does not distinguish between real time and virtual time then it can implement CNTVOFF as RAZ/WI. Otherwise CNTVOFF is a RW register, and ARM strongly recommends that the system only permits access to CNTVOFF from EL2 or higher.

I1.3.2 The CNTBaseN and CNTEL0BaseN frames

Table I1-4 on page I1-4971 shows the CNTBase*N* registers, in order of their offsets from the CNTBase*N* base address. Whether a frame includes a virtual timer is IMPLEMENTATION DEFINED. If it does not then memory at offsets 0x030-0x03C is RAZ/WI. Except for CNTEL0ACR and the CounterID<n> registers, equivalent registers are also implemented in a System register interface to the timer component of a Generic Timer.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Generic Timer memory-mapped register descriptions on page I3-5038 describes each of these registers.

Table I1-4 CNTBase*N* memory map

Offset	Register	Type	Description
0x000	CNTPCT[31:0][a]	RO	Physical Count register.
0x004	CNTPCT[63:32][a]	RO	
0x008	CNTVCT[31:0][a]	RO	Virtual Count register.
0x00C	CNTVCT[63:32][a]	RO	
0x010	CNTFRQ[a]	RO[c]	Counter Frequency register.
0x014	CNTEL0ACR	RW[b]	Counter EL0 Access Control Register, optional in the CNTBase*N* memory map.
0x018	CNTVOFF[31:0][a]	RO[c]	Virtual Offset register. If CNTVOFF<n> in the CNTCTLBase frame is a RW register, a read of this register returns the value of that register. Otherwise is RAZ.
0x01C	CNTVOFF[63:32][a]	RO[c]	
0x020	CNTP_CVAL[31:0][a]	RW	Physical Timer CompareValue register.
0x024	CNTP_CVAL[63:32][a]	RW	
0x028	CNTP_TVAL[a]	RW	Physical TimerValue register.
0x02C	CNTP_CTL[a]	RW	Physical Timer Control register.
0x030	CNTV_CVAL[31:0][a]	RW[b]	Virtual Timer CompareValue register, optional in the CNTBase*N* memory map.
0x034	CNTV_CVAL[63:32][a]	RW[b]	
0x038	CNTV_TVAL[a]	RW[b]	Virtual TimerValue register, optional in the CNTBase*N* memory map.
0x03C	CNTV_CTL[a]	RW[b]	Virtual Timer Control register, optional in the CNTBase*N* memory map.
0x040-0xFCF	-	res0	Reserved.
0xFD0-0xFFC	CounterID<n>	RO	Counter ID registers 0-11.

a. These registers are also defined in the System register interface to the Generic Timer, and therefore are also described in *Generic Timer registers* on page D7-2172 and *Generic Timer registers* on page G6-4654. The bit assignments of the registers are identical in the System register interface and in the memory-mapped system level interface.

b. Address is reserved, RAZ/WI if register not implemented

c. The CNTCTLBase frame includes a RW view of this register.

CNTTIDR controls whether the CNTBase*N* and CNTEL0Base*N* frames are implemented.

The CNTEL0BaseN frame

For any value of *N*, the layout of the registers in the CNTEL0Base*N* frame is identical to the CNTBase*N* frame, except that, in the CNTEL0Base*N* frame:

- CNTVOFF is never visible, and the memory at 0x018-0x01C is RAZ/WI.
- CNTEL0ACR is never visible, and the memory at 0x014 is RAZ/WI.
- If implemented in the CNTBase*N* frame, CNTEL0ACR controls whether CNTPCT, CNTVCT, CNTFRQ, the EL1 Physical Timer, and the Virtual Timer registers are visible in the CNTEL0Base*N* frame.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

If CNTEL0ACR is not implemented then these registers are not visible in the CNTEL0Base*N* frame, and their addresses in that frame are RAZ/WI.

If an implementation supports 64-bit atomic accesses, then CNTPCT, CNTVCT, CNTVOFF, CNTP_CVAL, and CNTV_CVAL must be accessible as atomic 64-bit values.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I1.4 Providing a complete set of counter and timer features

Using the general model for implementing a memory-mapped interface to the Generic Timer described in this section, the feature set of a System registers counter and timer, in an implementation that includes EL2 and EL3, can be implemented using the following set of timer frames:

- A CNTCTLBase control frame.
- The following CNTBase*N* timer frames:

  Frame 0 Accessible from Non-secure state, with second view and virtual capability. This provides the Non-secure EL1&0 timers.

  Frame 1 Accessible from Non-secure state, with no second view and no virtual capability. This provides the Non-secure EL2 timers.

  Frame 2 Accessible only from Secure state, with a second view but no virtual capability. This provides the Secure PL1&0 timers, meaning:
  - Compared to a PE where EL3 is using AArch32, it provides the only Secure state timer.
  - Compared to a PE where EL3 is using AArch64, it provides the Secure EL1&0 timer.

  Frame 3 Accessible only Secure state, with no second view and no virtual capability. This provides the Secure EL3 timers.

  Note

  This frame is not required for a memory-mapped timer that provides only the feature set of a PE for which EL3 is using AArch32.

In this implementation, the full set of implemented frames, and their configuration in the memory map, is as follows:

CNTCTLBase

The control frame. This frame is located in both Secure and Non-secure physical memory, and:
- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is not accessible.

CNTBase0 The first view of the Non-secure EL1&0 timers. This frame is located only in Non-secure physical memory, and:
- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible only at EL1.

CNTEL0Base0

The second view of CNTBase0, meaning it is the EL0 view of the Non-secure EL1&0 timers. This frame is located only in Non-secure physical memory, and:
- In the Secure EL1&0 translation regime, the architecture permits this frame to be accessible at EL1, or at EL1 and EL0, but does not require either of these options.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible at EL1 and EL0.

CNTBase1 The first and only view of the Non-secure EL2 timers. This frame is located only in Non-secure physical memory, and:
- When EL3 is using AArch64:
  - In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
  - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible only at PL1 (EL3).
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is not accessible.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

CNTBase2 The first view of the Secure EL1&0, or PL1&0 timers.

Note

In AArch64 state, these timers are always called the Secure EL1&0 timers. In AArch32 state they are usually called the Secure PL1&0 timers because, in AArch32 Secure state, whether some of the PE modes map to EL1 or to EL3 depends on whether EL3 is using AArch64 or is using AArch32, see *Execution privilege, Exception levels, and AArch32 Privilege levels* on page G4-3874.

This frame is located only in Secure physical memory, and:

- When EL3 is using AArch64:
  - In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
  - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible only at PL1 (EL3).
- Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

CNTEL0Base2

The second view of CNTBase2, meaning it is the EL0 view of the Secure EL1&0, or PL1&0, timers.

Note

See the Note in the description of the CNTBase2 frame for more information about the naming of these timers.

This frame is located only in Secure physical memory, and:

- When EL3 is using AArch64:
  - In the Secure EL1&0 translation regime, this frame is accessible at EL1 and EL0.
  - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible at PL1 (EL3) and EL0.
- Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

CNTBase3 The first and only view of the Non-secure EL3 timers. This frame is located only in Secure physical memory, and:

- When EL3 is using AArch64:
  - In the Secure EL1&0 translation regime, this frame is not accessible.
  - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, this frame is not accessible.
- Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

Note

About the Virtual Memory System Architecture (VMSA) on page D4-1646 describes the VMSAv8-64 translation regimes, and *About VMSAv8-32* on page G4-3876 describes the VMSAv8-32 translation regimes.

I1.5 Gray-count scheme for timer distribution scheme

The distribution of the Counter value using a Gray-code provides a relatively simple mechanism to avoid any danger of the count being sampled with an intermediate value even if the clocking is asynchronous. It has a further advantage that the distribution is relatively low power, since only one bit changes on the main distribution wires for each clock tick.

A suitable Gray-coding scheme can be achieved with the following logic:

Gray[N] = Count[N]

Gray[i] = (XOR(Gray[N:i+1])) XOR Count[i] for N–1 >= i >= 0

Count[i] = XOR(Gray[N:i]) for N >= i >= 0

This is for an N+1 bit counter, where Count is a conventional binary count value, and Gray is the corresponding Gray count value.

Note

This scheme has the advantage of being relatively simple to switch, in either direction, between operating with low-frequency and low-precision, and operating with high-frequency and high-precision. To achieve this, the ratio of the frequencies must be 2^n, where n is an integer. A switch-over can occur only on the $2n+1$ boundary to avoid losing the Gray-coding property on a switch-over.

Chapter I2
Recommended Memory-mapped Interfaces to the Performance Monitors

This chapter describes the recommended memory-mapped and external debug interfaces to the Performance Monitors. It contains the following section:

- *About the memory-mapped views of the Performance Monitors registers* on page I2-4978.

Note

Performance Monitors memory-mapped register descriptions on page I3-4987 describes the memory-mapped registers for the Performance Monitors.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I2.1 About the memory-mapped views of the Performance Monitors registers

An implementation can provide:

- Memory-mapped access to the Performance Monitors registers. Software running on any processor in a system can use this interface to access counters in the Performance Monitors.
- Access to the Performance Monitors registers through an external debug interface. A debugger can use this interface to access counters in the Performance Monitors.

  ARM recommends that any external debug interface is implemented as defined in the *ARM Debug Interface v5 Architecture Specification*.

  An external debug interface provides a memory-mapped view of the Performance Monitors registers.

Performance Monitors memory-mapped registers summary on page I3-4985 gives the memory map of these registers.

The following sections describe the memory-mapped views of the Performance Monitors registers:

- *Differences in the memory-mapped views of the Performance Monitors registers*.
- *Synchronization of changes to the memory-mapped views*.
- *Access permissions for memory-mapped views of the Performance Monitors*.

In this section, unless the context explicitly indicates otherwise, any reference to *a memory-mapped view* applies equally to a register view using:

- A access through an external debug interface.
- A memory-mapped access.

I2.1.1 Differences in the memory-mapped views of the Performance Monitors registers

A memory-mapped view of the Performance Monitors registers accesses the same registers as the System registers interface described in *Performance Monitors Extension registers* on page D5-1786, except that:

1. The PMSELR is accessible only in the System registers interface.
2. The PMCFGR, PMLAR, PMLSR, PMAUTHSTATUS, PMDEVARCH, PMDEVTYPE, PMPIDR0, PMPIDR1, PMPIDR2, PMPIDR3, PMPIDR4, PMCIDR0, PMCIDR1, PMCIDR2, and PMCIDR3 registers are accessible only in memory-mapped views. *Performance Monitors memory-mapped register descriptions* on page I3-4987 describes these registers.
3. The following controls do not affect the memory-mapped view:
   - PMSELR.
   - PMUSERENR.
   - HDCR.{TPM, TPMCR, HPMN}.

   Instead, see the register descriptions in Chapter I3 *Memory-Mapped System Control Register Descriptions*.

I2.1.2 Synchronization of changes to the memory-mapped views

If a Performance Monitor is visible in both System register and a memory-mapped views, and is accessed simultaneously through these two mechanisms, the behavior must be as if the access occurred atomically in any order. For more information, see *Synchronization of changes to the external debug registers* on page H8-4812.

I2.1.3 Access permissions for memory-mapped views of the Performance Monitors

For more information, see *External debug interface register access permissions* on page H8-4818.

Table I2-1 on page I2-4979 shows the access permissions for the Performance Monitors registers in a v8 Debug implementation. This table uses the following terms:

DLK When the OS Double Lock is locked, `DoubleLockStatus()` == TRUE, accesses to some registers produce an error. Applies to both interfaces.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

EPMAD When `AllowExternalPMUAccess()` == FALSE, external debug access is disabled. See also *Behavior of a not permitted memory-mapped access* on page H8-4817.

Error Indicates that the access gives an error response.

Default This shows the default access permissions, if none of the conditions in this list prevent access to the register.

Off When EDPRSR.PU == 0, the Core power domain is completely off, or in a low-power state where the Core power domain registers cannot be accessed.

Note

If debug power is off, then all external debug interface accesses return an error.

OSLK When the OS Lock is locked, OSLAR_EL1.OSLK == 1, accesses to some registers produces an error. This column shows the effect of this control on accesses using the external debug interface.

SLK This indicates the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software lock is locked. See *Register access permissions for memory-mapped accesses* on page H8-4816.

For all other accesses, this column is ignored.

- Indicates that the control has no effect on the behavior of the access:

- If no other control affects the behavior, the Default access behavior applies.
- However, another control might determine the behavior.

Table I2-1 Access permissions for the Performance Monitors registers

Offset	Register	Domain	Off	DLK	OSLK	EPMAD	Default	SLK
0x000+8xn	PMEVCNTR<n>_EL0[a]	Core	Error	Error	Error	Error	RW	RO
0x0F8	PMCCNTR_EL0[31:0]	Core	Error	Error	Error	Error	RW	RO

Table I2-1 Access permissions for the Performance Monitors registers (continued)

Offset	Register	Domain	Off	DLK	OSLK	EPMAD	Default	SLK
0xE20	PMCEID0_EL0	Core	Error	Error	Error	Error	RO	RO
0xE24	PMCEID1_EL0	Core	Error	Error	Error	Error	RO	RO
0xE80-0xEFC	Integration registers	-	Access is IMPLEMENTATION DEFINED					
0xF00-0xFFC	*Management registers and CoreSight compliance* on page K2-5387							

a. Implemented counters only. *n* is the counter number.
b. Only if the OPTIONAL PMSWINC_EL0 register is implemented in the external debug interface.

I2.1.4 Power domains and Performance Monitors registers reset

For ARMv8-A implementations, ARM recommends that Performance Monitors are implemented as part of the core power domain, not as part of a separate debug power domain. There is no interface to access the Performance Monitors registers when the core power domain is powered down.

A Warm or Cold reset sets the Performance Monitors registers to their reset values. An External Debug reset does not change the values of the Performance Monitors registers.

For more information about the reset scheme recommended for a v8 Debug implementation see Chapter H6 *Debug Reset and Powerdown Support*.

Table I2-2 shows the Performance Monitors register resets for writable register fields. The column headings use the following terms:

64 This is the architectural reset value when resetting into AArch64 state.

32 This is the architectural reset value when resetting into AArch32 state.

- This indicates an IMPLEMENTATION DEFINED reset value on the specified reset. This might be UNKNOWN.

Note

This table does not include:

- Read-only identification registers and fields that have a fixed value. In this case, the reset value is that fixed value. An example of this is PMCR_EL0.N.
- Write-only registers and fields that only have an effect on writes. These do not have a reset value. An example of this is PMSWINC_EL0.
- IMPLEMENTATION DEFINED registers. In this case, the reset domains are IMPLEMENTATION DEFINED. The reset values are IMPLEMENTATION DEFINED and might be UNKNOWN.

Table I2-2 Performance Monitors System register resets

Register	Domain	Field	64	32	Description
PMCR_EL0	Warm	DP	-	0	Disable PMCCNTR_EL0 when prohibited
		X	-	0	Export enable
		D	-	0	Clock divider
		E	0	0	Performance Monitors enable

Chapter I3
Memory-Mapped System Control Register Descriptions

This chapter describes the memory-mapped system control registers. It contains the following sections:

- *About the memory-mapped system control register descriptions* on page I3-4984.
- *Performance Monitors memory-mapped registers summary* on page I3-4985.
- *Performance Monitors memory-mapped register descriptions* on page I3-4987.
- *Generic Timer memory-mapped registers overview* on page I3-5037.
- *Generic Timer memory-mapped register descriptions* on page I3-5038.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.1 About the memory-mapped system control register descriptions

This chapter describes the memory-mapped system control registers other than the memory-mapped debug registers. That is, it describes:

The memory-mapped view of the Performance Monitors registers

- *Performance Monitors memory-mapped registers summary* on page I3-4985 lists these registers and describes their memory map.
- *Performance Monitors memory-mapped register descriptions* on page I3-4987 describes each of the memory-mapped registers.

Chapter I2 *Recommended Memory-mapped Interfaces to the Performance Monitors* describes the recommended interface to these registers.

Note

Chapter D5 *The Performance Monitors Extension* describes the Performance Monitors. The following sections describe the System register interfaces to the Performance Monitors:

- *Performance Monitors registers* on page D7-2132, for accesses from an Exception level that is using AArch64.
- *Performance Monitors registers* on page G6-4610, for accesses from an Exception level that is using AArch32.

The registers for the system-level Generic Timer component

Any implementation that includes the Generic Timer must include the memory-mapped system-level component described in Chapter I1 *System Level Implementation of the Generic Timer*. In this chapter:

- *Generic Timer memory-mapped registers overview* on page I3-5037 gives an overview of the registers, referring to Chapter I1 for more information.
- *Generic Timer memory-mapped register descriptions* on page I3-5038 describes each of the memory-mapped registers.

Note

Chapter D6 *The Generic Timer in AArch64 state* describes the Generic Timer component that is accessible using the System registers. The following sections describe the System register interfaces to that component:

- *Generic Timer registers* on page D7-2172, for accesses from an Exception level that is using AArch64.
- *Generic Timer registers* on page G6-4654, for accesses from an Exception level that is using AArch32.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.2 Performance Monitors memory-mapped registers summary

The locations of the registers in the memory-mapped view of the Performance Monitors are defined as offsets from a system-defined base address. *Performance Monitors memory-mapped register views* defines this memory map.

I3.2.1 Performance Monitors memory-mapped register views

Table I3-1 shows the memory-mapped view of the Performance Monitors registers. All other entries are reserved.

Note

- Counters that are reserved because HDCR.HPMN has been changed from its reset value remain visible in any memory-mapped view.
- The registers that relate to an implemented event counter, PMN*x*, are PMEVCNTR<n> and PMEVTYPER<n>.
- The mapping of the *Performance Monitors Event Counter Registers*, at offsets `0x000-0x0F4`, has changed compared to the mappings of the equivalent registers in ARMv7.

Each entry in the Name column links to the register description in *Performance Monitors memory-mapped register descriptions* on page I3-4987, and:

- If the *System register?* column of the table shows that the register is a System register, the memory-mapped interface provides a view of the System register described in:
  - *Performance Monitors registers* on page D7-2132, for the AArch64 System register
  - *Performance Monitors registers* on page G6-4610, for the AArch32 System register
- Otherwise, the register is accessible only using the memory-mapped interface.

Table I3-1 Performance Monitors memory-mapped register views

Offset	Type	Name	Description	System register?
`0x000`+8n	RW	PMEVCNTR<n>_EL0	Performance Monitors Event Counter Register.	Yes
`0x0F8` `0x0FC`	RW	PMCCNTR_EL0[31:0] PMCCNTR_EL0[63:32]	Performance Monitors Cycle Counter Register[a]	Yes
`0x400`+4n	RW	PMEVTYPER<n>_EL0	Performance Monitors Event Type and Filter Register.	Yes
`0x47C`	RW	PMCCFILTR_EL0	Performance Monitors Cycle Counter Filter Register	Yes
`0x600-0x6FC`	-	-	IMPLEMENTATION DEFINED	-
`0xA00-0xBFC`	-	-	IMPLEMENTATION DEFINED	-
`0xC00`	RW	PMCNTENSET_EL0	Performance Monitors Count Enable Set register	Yes
`0xC20`	RW	PMCNTENCLR_EL0	Performance Monitors Count Enable Clear register	Yes

`0xC60`	RW	PMINTENCLR_EL1	Performance Monitors Interrupt Enable Clear register	Yes
`0xC80`	RW	PMOVSCLR_EL0	Performance Monitors Overflow Flag Status Clear register	Yes
`0xCA0`	WO	PMSWINC_EL0	Performance Monitors Software Increment register	Yes
`0xCC0`	RW	PMOVSSET_EL0	Performance Monitors Overflow Flag Status Set register	Yes
`0xD80-0xDFC`	-	-	IMPLEMENTATION DEFINED	-

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Table I3-1 Performance Monitors memory-mapped register views (continued)

Offset	Type	Name	Description	System register?
0xE00	RO	PMCFGR	Performance Monitors Configuration Register	No
0xE04	RW	PMCR_EL0	Performance Monitors Control Register	Yes
0xE20	RO	PMCEID0_EL0	Performance Monitors Common Event Identification register 0	Yes
0xE24	RO	PMCEID1_EL0	Performance Monitors Common Event Identification register 1	Yes
0xE80-0xEFC	-	-	IMPLEMENTATION DEFINED	-
0xF00	RW	PMITCTRL[b]	Integration Model Control registers	No
0xFA8	RO	PMDEVAFF0[b]	Device Affinity registers	No
0xFAC	RO	PMDEVAFF1[b]		
0xFB0	WO	PMLAR[b, c]	Lock Access register	No
0xFB4	RO	PMLSR[b, c]	Lock Status register	No
0XFB8	RO	PMAUTHSTATUS[b]	Authentication Status register	No
0xFBC	RO	PMDEVARCH[b]	Device Architecture register	No
0xFCC	RO	PMDEVTYPE[b]	Device Type register	No
0xFD0	RO	PMPIDR4[b]	Peripheral ID registers	No
0xFE0	RO	PMPIDR0[b]		
0xFE4	RO	PMPIDR1[b]		
0xFE8	RO	PMPIDR2[b]		
0xFEC	RO	PMPIDR3[b]		
0xFF0	RO	PMCIDR0[b]	Component ID registers	No
0xFF4	RO	PMCIDR1[b]		
0xFF8	RO	PMCIDR2[b]		
0xFFC	RO	PMCIDR3[b]		

a. The interface must support at least single-copy atomic 32-bit accesses. If single-copy atomic 64-bit access to the registers is not possible, software must use a high-low-high read access to read the counter value if the counter is enabled.

b. CoreSight interface registers, see *Management registers and CoreSight compliance* on page K2-5387.

c. The Software lock registers are defined as part of CoreSight compliance, but their contents depend on the type of access that is made and whether the OPTIONAL Software lock is implemented. See the register description for details.

I3.3 Performance Monitors memory-mapped register descriptions

This section describes the Performance Monitoring registers. *Performance Monitors memory-mapped registers summary* on page I3-4985 lists these registers in their memory map.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.1 PMAUTHSTATUS, Performance Monitors Authentication Status register

The PMAUTHSTATUS characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for Performance Monitors.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMAUTHSTATUS is in the Debug power domain.

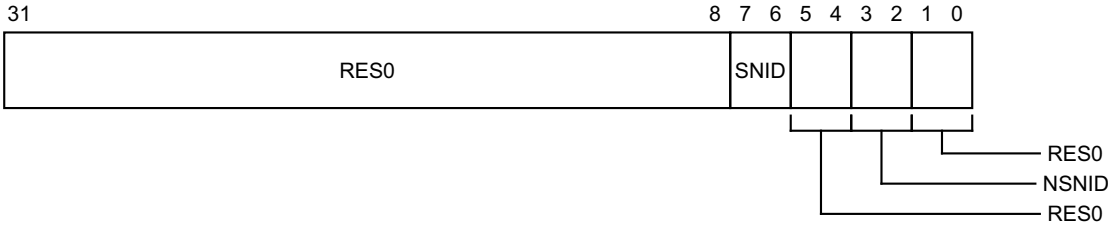
This register is OPTIONAL, and is required for CoreSight compliance. ARM recommends that this register is implemented.

Attributes

PMAUTHSTATUS is a 32-bit register.

Field descriptions

The PMAUTHSTATUS bit assignments are:



Bits [31:8]

Reserved, RES0.

SNID, bits [7:6]

Holds the same value as DBGAUTHSTATUS_EL1.SNID.

Bits [5:4]

Reserved, RES0.

NSNID, bits [3:2]

Holds the same value as DBGAUTHSTATUS_EL1.NSNID.

Bits [1:0]

Reserved, RES0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the PMAUTHSTATUS:

PMAUTHSTATUS can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFB8

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.2 PMCCFILTR_EL0, Performance Monitors Cycle Counter Filter Register

The PMCCFILTR_EL0 characteristics are:

Purpose

Determines the modes in which the Cycle Counter, PMCCNTR_EL0, increments.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMCCFILTR_EL0 is architecturally mapped to AArch64 System register PMCCFILTR_EL0.

External register PMCCFILTR_EL0 is architecturally mapped to AArch32 System register PMCCFILTR.

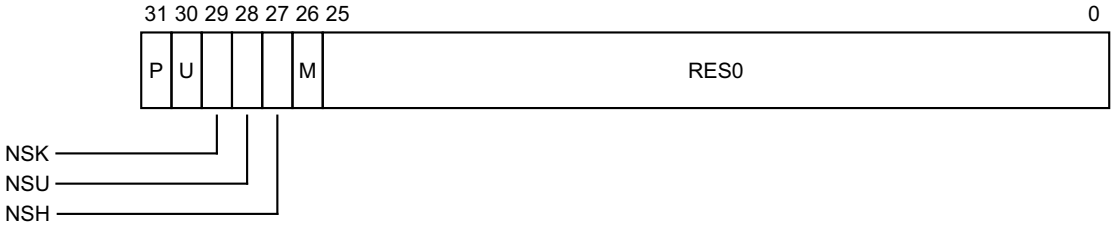
PMCCFILTR_EL0 is in the Core power domain.

Attributes

PMCCFILTR_EL0 is a 32-bit register.

Field descriptions

The PMCCFILTR_EL0 bit assignments are:



P, bit [31]

EL1 modes filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

`0` Count cycles in EL1.

`1` Do not count cycles in EL1.

U, bit [30]

EL0 filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

`0` Count cycles in EL0.

`1` Do not count cycles in EL0.

NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Non-secure EL1 are counted.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Otherwise, cycles in Non-secure EL1 are not counted.

NSU, bit [28]

Non-secure User mode filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, cycles in Non-secure EL0 are counted.

Otherwise, cycles in Non-secure EL0 are not counted.

NSH, bit [27]

Non-secure Hyp modes filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

`0` Do not count cycles in EL2.

`1` Count cycles in EL2.

M, bit [26]

Secure EL3 filtering bit. Most applications can ignore this bit and set the value to zero. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Secure EL3 are counted.

Otherwise, cycles in Secure EL3 are not counted.

Bits [25:0]

Reserved, RES0.

Accessing the PMCCFILTR_EL0:

PMCCFILTR_EL0 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	0x47C

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.3 PMCCNTR_EL0, Performance Monitors Cycle Counter

The PMCCNTR_EL0 characteristics are:

Purpose

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles. See *Time as measured by the Performance Monitors cycle counter* on page D5-1751 for more information.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMCCNTR_EL0 is architecturally mapped to AArch64 System register PMCCNTR_EL0.

External register PMCCNTR_EL0 is architecturally mapped to AArch32 System register PMCCNTR.

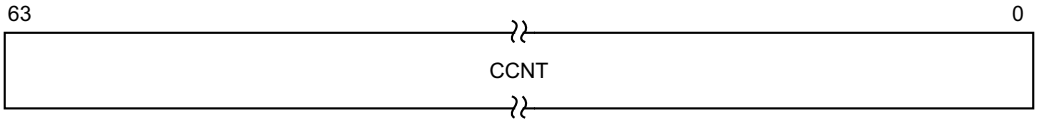
PMCCNTR_EL0 is in the Core power domain.

Attributes

PMCCNTR_EL0 is a 64-bit register.

Field descriptions

The PMCCNTR_EL0 bit assignments are:



CCNT, bits [63:0]

Cycle count. Depending on the values of PMCR_EL0.{LC,D}, the cycle count increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to PMCR_EL0.C sets this field to 0.

Accessing the PMCCNTR_EL0:

PMCCNTR_EL0[31:0] can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	0x0F8

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

PMCCNTR_EL0[63:32] can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	0x0FC

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.4 PMCEID0_EL0, Performance Monitors Common Event Identification register 0

The PMCEID0_EL0 characteristics are:

Purpose

Defines which common architectural and common microarchitectural feature events are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RO

Configurations

External register PMCEID0_EL0 is architecturally mapped to AArch64 System register PMCEID0_EL0.

External register PMCEID0_EL0 is architecturally mapped to AArch32 System register PMCEID0.

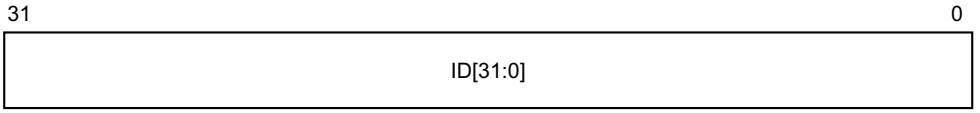
PMCEID0_EL0 is in the Core power domain.

Attributes

PMCEID0_EL0 is a 32-bit register.

Field descriptions

The PMCEID0_EL0 bit assignments are:



ID[31:0], bits [31:0]

PMCEID0_EL0[n] maps to event n. For a list of event numbers and descriptions, see *Events, event numbers, and mnemonics* on page D5-1764.

For each bit:

`0` The common event is not implemented.

`1` The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

Accessing the PMCEID0_EL0:

PMCEID0_EL0 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xE20`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.5 PMCEID1_EL0, Performance Monitors Common Event Identification register 1

The PMCEID1_EL0 characteristics are:

Purpose

Defines which common architectural and common microarchitectural feature events are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RO

Configurations

External register PMCEID1_EL0 is architecturally mapped to AArch64 System register PMCEID1_EL0.

External register PMCEID1_EL0 is architecturally mapped to AArch32 System register PMCEID1.

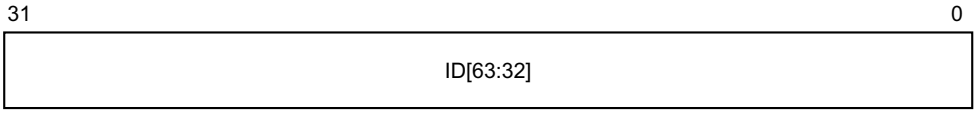
PMCEID1_EL0 is in the Core power domain.

Attributes

PMCEID1_EL0 is a 32-bit register.

Field descriptions

The PMCEID1_EL0 bit assignments are:



ID[63:32], bits [31:0]

PMCEID1_EL0[n] maps to event (n + 32). For a list of event numbers and descriptions, see *Events, event numbers, and mnemonics* on page D5-1764.

For each bit:

`0` The common event is not implemented.

`1` The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

Accessing the PMCEID1_EL0:

PMCEID1_EL0 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xE24`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.6 PMCFGR, Performance Monitors Configuration Register

The PMCFGR characteristics are:

Purpose

Contains PMU-specific configuration data.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RO

Configurations

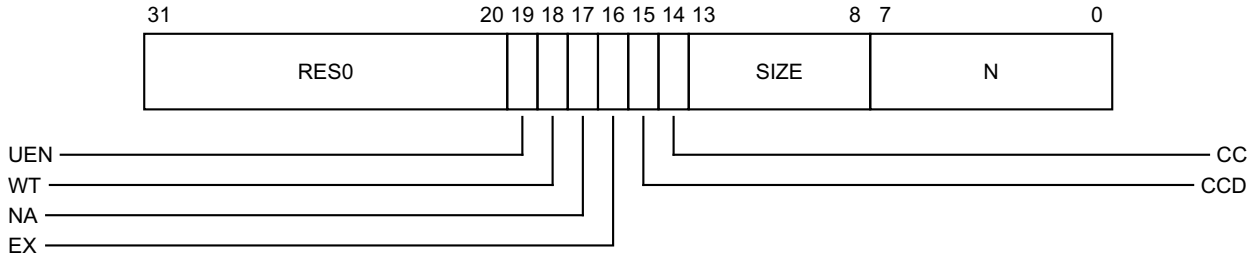
PMCFGR is in the Core power domain.

Attributes

PMCFGR is a 32-bit register.

Field descriptions

The PMCFGR bit assignments are:



Bits [31:20]

Reserved, RES0.

UEN, bit [19]

User-mode Enable Register supported. PMUSERENR_EL0 is not visible in the external debug interface, so this bit is RES0.

WT, bit [18]

This feature is not supported, so this bit is RES0.

NA, bit [17]

This feature is not supported, so this bit is RES0.

EX, bit [16]

Export supported. Value is IMPLEMENTATION DEFINED.

`0` PMCR_EL0.X is RES0.

`1` PMCR_EL0.X is read/write.

CCD, bit [15]

Cycle counter has prescale. This is RES1 if AArch32 is supported at any EL, and RES0 otherwise.

`0` PMCR_EL0.D is RES0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

1 PMCR_EL0.D is read/write.

CC, bit [14]

Dedicated cycle counter (counter 31) supported. This bit is RES1.

SIZE, bits [13:8]

Size of counters. This field determines the spacing of counters in the memory-map.

In ARMv8 the counters are at doubleword-aligned addresses, and the largest counter is 64-bits, so this field is `0b111111`.

N, bits [7:0]

Number of counters implemented in addition to the cycle counter, PMCCNTR_EL0. The maximum number of event counters is 31, so bits[7:5] are always RES0.

`00000000` Only PMCCNTR_EL0 implemented.

`00000001` PMCCNTR_EL0 plus one event counter implemented.

and so on up to `00011111`, which indicates PMCCNTR_EL0 and 31 event counters implemented.

Accessing the PMCFGR:

PMCFGR can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xE00`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.7 PMCIDR0, Performance Monitors Component Identification Register 0

The PMCIDR0 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMCIDR0 is in the Debug power domain.

PMCIDR0 is optional to implement in the external register interface.

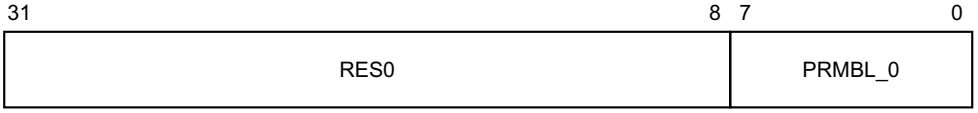
This register is required for CoreSight compliance.

Attributes

PMCIDR0 is a 32-bit register.

Field descriptions

The PMCIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_0, bits [7:0]

Preamble. Must read as `0x0D`.

Accessing the PMCIDR0:

PMCIDR0 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xFF0`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.8 PMCIDR1, Performance Monitors Component Identification Register 1

The PMCIDR1 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMCIDR1 is in the Debug power domain.

PMCIDR1 is optional to implement in the external register interface.

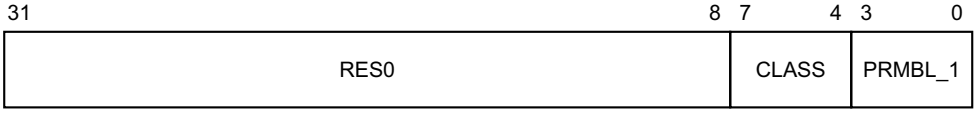
This register is required for CoreSight compliance.

Attributes

PMCIDR1 is a 32-bit register.

Field descriptions

The PMCIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

CLASS, bits [7:4]

Component class. Reads as `0x9`, debug component.

PRMBL_1, bits [3:0]

Preamble. RAZ.

Accessing the PMCIDR1:

PMCIDR1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xFF4`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.9 PMCIDR2, Performance Monitors Component Identification Register 2

The PMCIDR2 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMCIDR2 is in the Debug power domain.

PMCIDR2 is optional to implement in the external register interface.

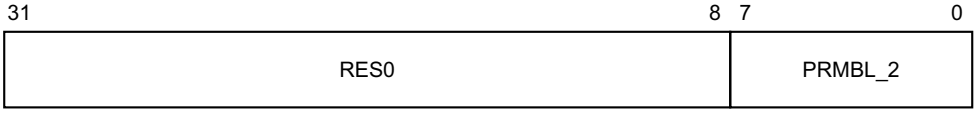
This register is required for CoreSight compliance.

Attributes

PMCIDR2 is a 32-bit register.

Field descriptions

The PMCIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

Preamble. Must read as `0x05`.

Accessing the PMCIDR2:

PMCIDR2 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xFF8`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.10 PMCIDR3, Performance Monitors Component Identification Register 3

The PMCIDR3 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMCIDR3 is in the Debug power domain.

PMCIDR3 is optional to implement in the external register interface.

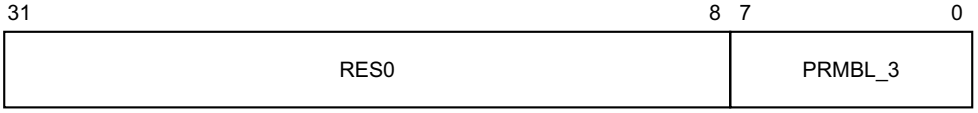
This register is required for CoreSight compliance.

Attributes

PMCIDR3 is a 32-bit register.

Field descriptions

The PMCIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_3, bits [7:0]

Preamble. Must read as `0xB1`.

Accessing the PMCIDR3:

PMCIDR3 can be accessed through the memory-mapped interface and the external debug interface:

I3.3.11 PMCNTENCLR_EL0, Performance Monitors Count Enable Clear register

The PMCNTENCLR_EL0 characteristics are:

Purpose

Disables the Cycle Count Register, PMCCNTR_EL0, and any implemented event counters PMEVCNTR<x>. Reading this register shows which counters are enabled.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMCNTENCLR_EL0 is architecturally mapped to AArch64 System register PMCNTENCLR_EL0.

External register PMCNTENCLR_EL0 is architecturally mapped to AArch32 System register PMCNTENCLR.

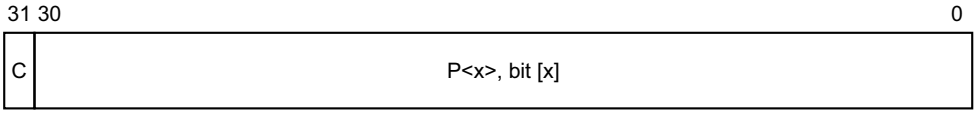
PMCNTENCLR_EL0 is in the Core power domain.

Attributes

PMCNTENCLR_EL0 is a 32-bit register.

Field descriptions

The PMCNTENCLR_EL0 bit assignments are:



C, bit [31]

PMCCNTR_EL0 disable bit. Disables the cycle counter register. Possible values are:

0 When read, means the cycle counter is disabled. When written, has no effect.

1 When read, means the cycle counter is enabled. When written, disables the cycle counter.

P<x>, bit [x], for x = 0 to 30

Event counter disable bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI. N is the value in PMCFGR.N.

Possible values of each bit are:

0 When read, means that PMEVCNTR<x> is disabled. When written, has no effect.

1 When read, means that PMEVCNTR<x> is enabled. When written, disables PMEVCNTR<x>.

I3.3.12 PMCNTENSET_EL0, Performance Monitors Count Enable Set register

The PMCNTENSET_EL0 characteristics are:

Purpose

Enables the Cycle Count Register, PMCCNTR_EL0, and any implemented event counters PMEVCNTR<x>. Reading this register shows which counters are enabled.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMCNTENSET_EL0 is architecturally mapped to AArch64 System register PMCNTENSET_EL0.

External register PMCNTENSET_EL0 is architecturally mapped to AArch32 System register PMCNTENSET.

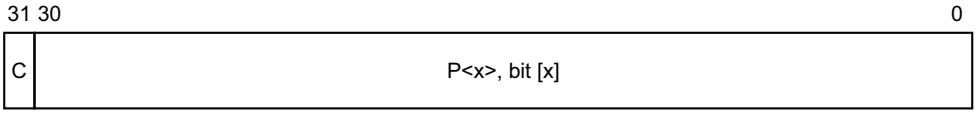
PMCNTENSET_EL0 is in the Core power domain.

Attributes

PMCNTENSET_EL0 is a 32-bit register.

Field descriptions

The PMCNTENSET_EL0 bit assignments are:



C, bit [31]

PMCCNTR_EL0 enable bit. Enables the cycle counter register. Possible values are:

0 When read, means the cycle counter is disabled. When written, has no effect.

1 When read, means the cycle counter is enabled. When written, enables the cycle counter.

P<x>, bit [x], for x = 0 to 30

Event counter enable bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI. N is the value in PMCFGR.N.

Possible values of each bit are:

0 When read, means that PMEVCNTR<x> is disabled. When written, has no effect.

1 When read, means that PMEVCNTR<x> event counter is enabled. When written, enables PMEVCNTR<x>.

I3.3.13 PMCR_EL0, Performance Monitors Control Register

The PMCR_EL0 characteristics are:

Purpose

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMCR_EL0[6:0] is architecturally mapped to AArch32 System register PMCR[6:0].

External register PMCR_EL0[6:0] is architecturally mapped to AArch64 System register PMCR_EL0[6:0].

PMCR_EL0 is in the Core power domain.

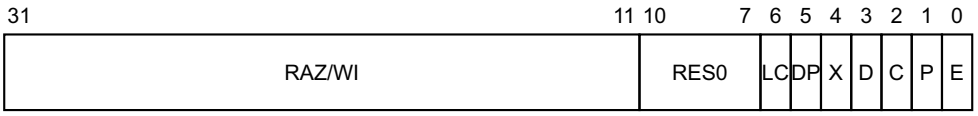
This register is only partially mapped to the internal PMCR System register. An external agent must use other means to discover the information held in PMCR[31:11], such as accessing PMCFGR and the ID registers.

Attributes

PMCR_EL0 is a 32-bit register.

Field descriptions

The PMCR_EL0 bit assignments are:



Bits [31:11]

Reserved. Hardware must implement this field as RAZ/WI. Software must not rely on the register reading as zero, and must use a read-modify-write sequence to update the register.

Bits [10:7]

Reserved, RES0.

LC, bit [6]

Long cycle counter enable. Determines which PMCCNTR_EL0 bit generates an overflow recorded by PMOVSR[31].

`0` Cycle counter overflow on increment that changes PMCCNTR_EL0[31] from 1 to 0.

`1` Cycle counter overflow on increment that changes PMCCNTR_EL0[63] from 1 to 0.

ARM deprecates use of PMCR_EL0.LC = 0.

In an AArch64-only implementation, this field is RES1.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

DP, bit [5]

Disable cycle counter when event counting is prohibited. The possible values of this bit are:

0 PMCCNTR_EL0, if enabled, counts when event counting is prohibited.

1 PMCCNTR_EL0 does not count when event counting is prohibited.

Event counting is prohibited when ProfilingProhibited(IsSecure(),PSTATE.EL) == TRUE.

This bit is RW.

If EL3 is not implemented, this field is RES0.

X, bit [4]

Enable export of events in an IMPLEMENTATION DEFINED event stream. The possible values of this bit are:

0 Do not export events.

1 Export events where not prohibited.

This bit is used to permit events to be exported to another debug device, such as an OPTIONAL trace macrocell, over an event bus. If the implementation does not include such an event bus, this bit is RAZ/WI.

This bit does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the PE.

If the implementation does not include an exported event stream, this bit is RAZ/WI. Otherwise this bit is RW.

D, bit [3]

Clock divider. The possible values of this bit are:

0 When enabled, PMCCNTR_EL0 counts every clock cycle.

1 When enabled, PMCCNTR_EL0 counts once every 64 clock cycles.

This bit is RW.

If PMCR_EL0.LC == 1, this bit is ignored and the cycle counter counts every clock cycle.

ARM deprecates use of PMCR.D = 1.

In an AArch64-only implementation, this field is RES0.

C, bit [2]

Cycle counter reset. This bit is WO. The effects of writing to this bit are:

0 No action.

1 Reset PMCCNTR_EL0 to zero.

This bit is always RAZ.

Resetting PMCCNTR_EL0 does not clear the PMCCNTR_EL0 overflow bit to 0.

P, bit [1]

Event counter reset. This bit is WO. The effects of writing to this bit are:

0 No action.

1 Reset all event counters, not including PMCCNTR_EL0, to zero.

This bit is always RAZ.

Resetting the event counters does not clear any overflow bits to 0.

E, bit [0]

Enable. The possible values of this bit are:

0 All counters, including PMCCNTR_EL0, are disabled.

1 All counters are enabled by PMCNTENSET_EL0.

This bit is RW.

I3.3.14 PMDEVAFF0, Performance Monitors Device Affinity register 0

The PMDEVAFF0 characteristics are:

Purpose

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the Performance Monitor component relates to.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMDEVAFF0 is in the Debug power domain.

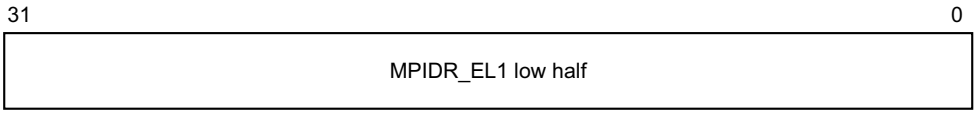
PMDEVAFF0 is optional to implement in the external register interface.

Attributes

PMDEVAFF0 is a 32-bit register.

Field descriptions

The PMDEVAFF0 bit assignments are:



Bits [31:0]

MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented Exception level.

Accessing the PMDEVAFF0:

PMDEVAFF0 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFA8

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.15 PMDEVAFF1, Performance Monitors Device Affinity register 1

The PMDEVAFF1 characteristics are:

Purpose

Copy of the high half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the Performance Monitor component relates to.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMDEVAFF1 is in the Debug power domain.

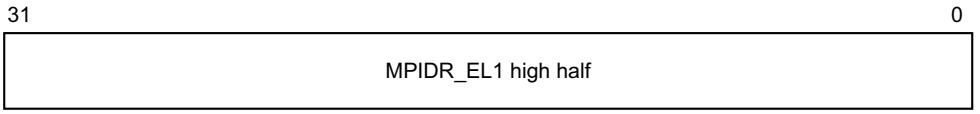
PMDEVAFF1 is optional to implement in the external register interface.

Attributes

PMDEVAFF1 is a 32-bit register.

Field descriptions

The PMDEVAFF1 bit assignments are:



Bits [31:0]

MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented Exception level.

Accessing the PMDEVAFF1:

PMDEVAFF1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFAC

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.16 PMDEVARCH, Performance Monitors Device Architecture register

The PMDEVARCH characteristics are:

Purpose

Identifies the programmers' model architecture of the Performance Monitor component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMDEVARCH is in the Debug power domain.

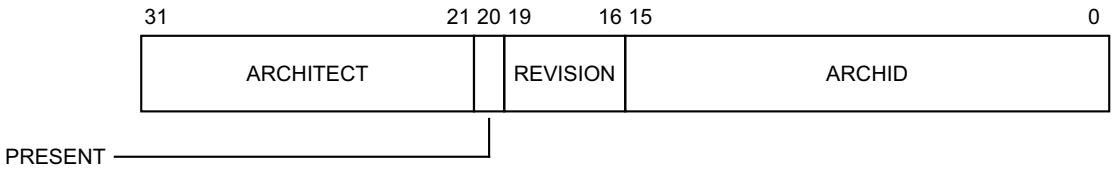
PMDEVARCH is optional to implement in the external register interface.

Attributes

PMDEVARCH is a 32-bit register.

Field descriptions

The PMDEVARCH bit assignments are:



ARCHITECT, bits [31:21]

Defines the architecture of the component. For Performance Monitors, this is ARM Limited.

Bits [31:28] are the JEP 106 continuation code, `0x4`.

Bits [27:21] are the JEP 106 ID code, `0x3B`.

PRESENT, bit [20]

When set to 1, indicates that the DEVARCH is present.

This field is 1 in ARMv8.

REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by ARM this is the minor revision.

For Performance Monitors, the revision defined by ARMv8 is `0x0`.

All other values are reserved.

ARCHID, bits [15:0]

Defines this part to be an ARMv8 debug component. For architectures defined by ARM this is further subdivided.

For Performance Monitors:

- Bits [15:12] are the architecture version, `0x2`.
- Bits [11:0] are the architecture part number, `0xA16`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

This corresponds to Performance Monitors architecture version PMUv3.

Note

The PMUv3 memory-mapped programmers' model can be used by devices other than ARMv8 processors. Software must determine whether the PMU is attached to an ARMv8 processor by using the PMDEVAFF0 and PMDEVAFF1 registers to discover the affinity of the PMU to any ARMv8 processors.

Accessing the PMDEVARCH:

PMDEVARCH can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFBC

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.17 PMDEVTYPE, Performance Monitors Device Type register

The PMDEVTYPE characteristics are:

Purpose

Indicates to a debugger that this component is part of a PEs performance monitor interface.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMDEVTYPE is in the Debug power domain.

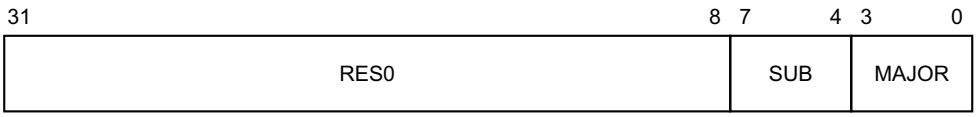
PMDEVTYPE is optional to implement in the external register interface.

Attributes

PMDEVTYPE is a 32-bit register.

Field descriptions

The PMDEVTYPE bit assignments are:



Bits [31:8]

Reserved, RES0.

SUB, bits [7:4]

Subtype. Must read as `0x1` to indicate this is a component within a PE.

MAJOR, bits [3:0]

Major type. Must read as `0x6` to indicate this is a performance monitor component.

Accessing the PMDEVTYPE:

PMDEVTYPE can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xFCC`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.18 PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n>_EL0 characteristics are:

Purpose

Holds event counter n, which counts events, where n is 0 to 30.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

External accesses to the performance monitors ignore PMUSERENR_EL0 and, if implemented, MDCR_EL2.{TPM, TPMCR, HPMN} and MDCR_EL3.TPM. This means that all counters are accessible regardless of the current EL or privilege of the access.

Configurations

External register PMEVCNTR<n>_EL0 is architecturally mapped to AArch64 System register PMEVCNTR<n>_EL0.

External register PMEVCNTR<n>_EL0 is architecturally mapped to AArch32 System register PMEVCNTR<n>.

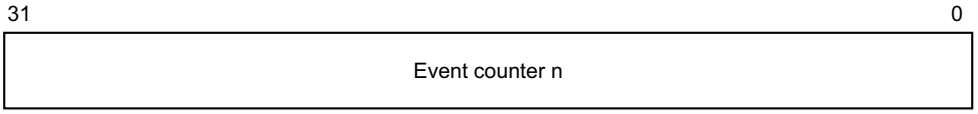
PMEVCNTR<n>_EL0 is in the Core power domain.

Attributes

PMEVCNTR<n>_EL0 is a 32-bit register.

Field descriptions

The PMEVCNTR<n>_EL0 bit assignments are:



Bits [31:0]

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

Accessing the PMEVCNTR<n>_EL0:

PMEVCNTR<n>_EL0 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0x000` + 8n

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.19 PMEVTYPER<n>_EL0, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<n>_EL0 characteristics are:

Purpose

Configures event counter n, where n is 0 to 30.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMEVTYPER<n>_EL0 is architecturally mapped to AArch64 System register PMEVTYPER<n>_EL0.

External register PMEVTYPER<n>_EL0 is architecturally mapped to AArch32 System register PMEVTYPER<n>.

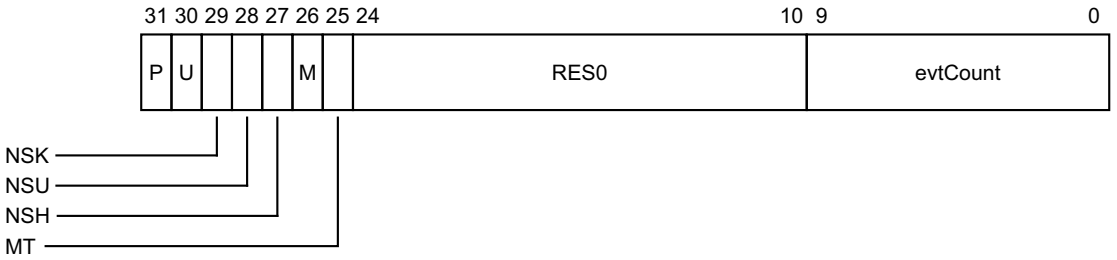
PMEVTYPER<n>_EL0 is in the Core power domain.

Attributes

PMEVTYPER<n>_EL0 is a 32-bit register.

Field descriptions

The PMEVTYPER<n>_EL0 bit assignments are:



P, bit [31]

EL1 modes filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

`0` Count events in EL1.

`1` Do not count events in EL1.

U, bit [30]

EL0 filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

`0` Count events in EL0.

`1` Do not count events in EL0.

NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

If the value of this bit is equal to the value of P, events in Non-secure EL1 are counted.

Otherwise, events in Non-secure EL1 are not counted.

NSU, bit [28]

Non-secure User mode filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, events in Non-secure EL0 are counted.

Otherwise, events in Non-secure EL0 are not counted.

NSH, bit [27]

Non-secure Hyp modes filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

`0` Do not count events in EL2.

`1` Count events in EL2.

M, bit [26]

Secure EL3 filtering bit. Most applications can ignore this bit and set the value to zero. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Secure EL3 are counted.

Otherwise, events in Secure EL3 are not counted.

MT, bit [25]

Multithreading. When the implementation is multi-threaded, the valid values for this bit are:

`0` Count events only on controlling PE.

`1` Count events from any PE with the same affinity at level 1 and above as this PE.

When the implementation is not multi-threaded, this bit is RES0.

Note

- Events from a different thread of a multi-threaded implementation are not Attributable to the thread counting the event.
- An implementation is described as multi-threaded when the lowest level of affinity consists of logical PEs that are implemented using a multi-threading type approach. That is, the performance of PEs at the lowest affinity level is highly interdependent. On such an implementation, the value of MPIDR.MT, when read at the highest implemented Exception level, is 1.

Bits [24:10]

Reserved, RES0.

evtCount, bits [9:0]

Event to count. The event number of the event that is counted by event counter PMEVCNTR<n>_EL0.

Software must program this field with an event defined by the processor or a common event defined by the architecture.

If evtCount is programmed to an event that is reserved or not implemented, the behavior depends on the event type.

For common architectural and microarchitectural events:

- No events are counted.
- The value read back on evtCount is the value written.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

For IMPLEMENTATION DEFINED events:

- It is UNPREDICTABLE what event, if any, is counted. UNPREDICTABLE in this case means the event must not expose privileged information.
- The value read back on evtCount is an UNKNOWN value with the same effect.

ARM recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATION DEFINED events, then no event is counted and the value read back on evtCount is the value written.

Accessing the PMEVTYPER<n>_EL0:

PMEVTYPER<n>_EL0 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0x400` + 4n

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.20 PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR_EL1 characteristics are:

Purpose

Disables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR_EL0, and the event counters PMEVCNTR<n>_EL0. Reading the register shows which overflow interrupt requests are enabled.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMINTENCLR_EL1 is architecturally mapped to AArch64 System register PMINTENCLR_EL1.

External register PMINTENCLR_EL1 is architecturally mapped to AArch32 System register PMINTENCLR.

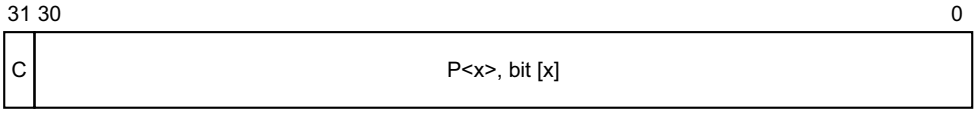
PMINTENCLR_EL1 is in the Core power domain.

Attributes

PMINTENCLR_EL1 is a 32-bit register.

Field descriptions

The PMINTENCLR_EL1 bit assignments are:



C, bit [31]

PMCCNTR_EL0 overflow interrupt request disable bit. Possible values are:

`0` When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

`1` When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request.

P<x>, bit [x], for x = 0 to 30

Event counter overflow interrupt request disable bit for PMEVCNTR<x>_EL0.

Bits [30:N] are RAZ/WI. N is the value in PMCFGR.N.

Possible values are:

`0` When read, means that the PMEVCNTR<x>_EL0 event counter interrupt request is disabled. When written, has no effect.

`1` When read, means that the PMEVCNTR<x>_EL0 event counter interrupt request is enabled. When written, disables the PMEVCNTR<x>_EL0 interrupt request.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the PMINTENCLR_EL1:

PMINTENCLR_EL1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xC60

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.21 PMINTENSET_EL1, Performance Monitors Interrupt Enable Set register

The PMINTENSET_EL1 characteristics are:

Purpose

Enables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR_EL0, and the event counters PMEVCNTR<n>_EL0. Reading the register shows which overflow interrupt requests are enabled.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMINTENSET_EL1 is architecturally mapped to AArch64 System register PMINTENSET_EL1.

External register PMINTENSET_EL1 is architecturally mapped to AArch32 System register PMINTENSET.

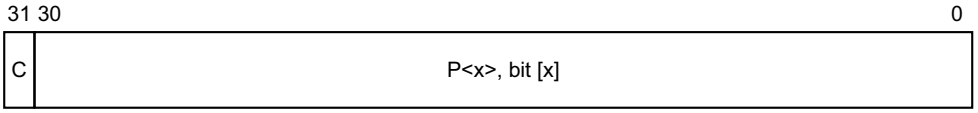
PMINTENSET_EL1 is in the Core power domain.

Attributes

PMINTENSET_EL1 is a 32-bit register.

Field descriptions

The PMINTENSET_EL1 bit assignments are:



C, bit [31]

PMCCNTR_EL0 overflow interrupt request enable bit. Possible values are:

`0` When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

`1` When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request.

P<x>, bit [x], for x = 0 to 30

Event counter overflow interrupt request enable bit for PMEVCNTR<x>_EL0.

Bits [30:N] are RAZ/WI. N is the value in PMCFGR.N.

Possible values are:

`0` When read, means that the PMEVCNTR<x>_EL0 event counter interrupt request is disabled. When written, has no effect.

`1` When read, means that the PMEVCNTR<x>_EL0 event counter interrupt request is enabled. When written, enables the PMEVCNTR<x>_EL0 interrupt request.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the PMINTENSET_EL1:

PMINTENSET_EL1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xC40

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.22 PMITCTRL, Performance Monitors Integration mode Control register

The PMITCTRL characteristics are:

Purpose

Enables the Performance Monitors to switch from default mode into integration mode, where test software can control directly the inputs and outputs of the PE, for integration testing or topology detection.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	Default
IMP DEF	IMP DEF	IMP DEF	RW

Configurations

It is IMPLEMENTATION DEFINED whether PMITCTRL is in the Core power domain or in the Debug power domain.

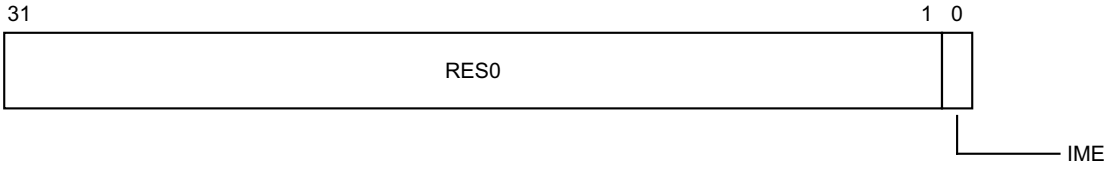
PMITCTRL is optional to implement in the external register interface.

Attributes

PMITCTRL is a 32-bit register.

Field descriptions

The PMITCTRL bit assignments are:



Bits [31:1]

Reserved, RES0.

IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

`0` Normal operation.

`1` Integration mode enabled.

When this register has an architecturally-defined reset value, this field resets to `0`.

Accessing the PMITCTRL:

PMITCTRL can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xF00`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.23 PMLAR, Performance Monitors Lock Access Register

The PMLAR characteristics are:

Purpose

Allows or disallows access to the Performance Monitors registers through a memory-mapped interface.

Usage constraints

This register is accessible as follows:

Default
WO

Configurations

PMLAR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software lock can be implemented as part of CoreSight compliance.

PMLAR ignores writes if the Software lock is not implemented and ignores writes for other accesses to the external debug interface.

The Software lock provides a lock to prevent memory-mapped writes to the Performance Monitors registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Performance Monitors registers. It does not, and cannot, prevent all accidental or malicious damage.

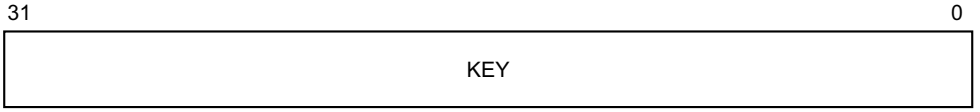
Software uses PMLAR to set or clear the lock, and PMLSR to check the current status of the lock.

Attributes

PMLAR is a 32-bit register.

Field descriptions

The PMLAR bit assignments are:



KEY, bits [31:0]

Lock Access control. Writing the key value `0xC5ACCE55` to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

Accessing the PMLAR:

PMLAR can be accessed through the memory-mapped interface:

Component	Offset
PMU	`0xFB0`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.24 PMLSR, Performance Monitors Lock Status Register

The PMLSR characteristics are:

Purpose

Indicates the current status of the software lock for Performance Monitors registers.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

PMLSR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software lock can be implemented as part of CoreSight compliance.

PMLSR is RAZ if the Software lock is not implemented and is RAZ for other accesses to the external debug interface.

The Software lock provides a lock to prevent memory-mapped writes to the Performance Monitors registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Performance Monitors registers. It does not, and cannot, prevent all accidental or malicious damage.

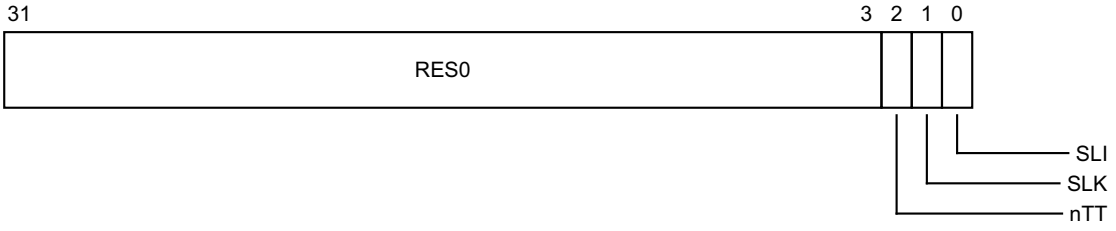
Software uses PMLAR to set or clear the lock, and PMLSR to check the current status of the lock.

Attributes

PMLSR is a 32-bit register.

Field descriptions

The PMLSR bit assignments are:



Bits [31:3]

Reserved, RES0.

nTT, bit [2]

Not thirty-two bit access required. RAZ.

SLK, bit [1]

Software lock status for this component. For an access to LSR that is not a memory-mapped access, or when the software lock is not implemented, this field is RES0.

For memory-mapped accesses when the software lock is implemented, possible values of this field are:

`0` Lock clear. Writes are permitted to this component's registers.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

`1` Lock set. Writes to this component's registers are ignored, and reads have no side effects.

When this register has an architecturally-defined reset value, this field resets to `1`.

SLI, bit [0]

Software lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are:

`0` Software lock not implemented or not memory-mapped access.

`1` Software lock implemented and memory-mapped access.

Accessing the PMLSR:

PMLSR can be accessed through the memory-mapped interface:

Component	Offset
PMU	`0xFB4`

I3.3.25 PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear register

The PMOVSCLR_EL0 characteristics are:

Purpose

Contains the state of the overflow bit for the Cycle Count Register, PMCCNTR_EL0, and each of the implemented event counters PMEVCNTR<x>. Writing to this register clears these bits.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMOVSCLR_EL0 is architecturally mapped to AArch64 System register PMOVSCLR_EL0.

External register PMOVSCLR_EL0 is architecturally mapped to AArch32 System register PMOVSR.

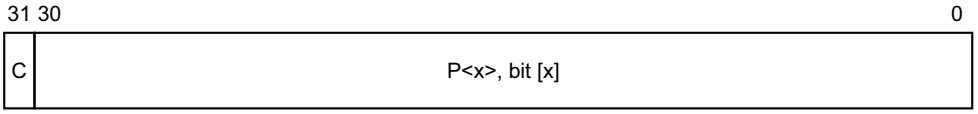
PMOVSCLR_EL0 is in the Core power domain.

Attributes

PMOVSCLR_EL0 is a 32-bit register.

Field descriptions

The PMOVSCLR_EL0 bit assignments are:



C, bit [31]

PMCCNTR_EL0 overflow bit. Possible values are:

`0` When read, means the cycle counter has not overflowed. When written, has no effect.

`1` When read, means the cycle counter has overflowed. When written, clears the overflow bit to 0.

PMCR_EL0.LC is used to control from which bit of PMCCNTR_EL0 (bit 31 or bit 63) an overflow is detected.

P<x>, bit [x], for x = 0 to 30

Event counter overflow clear bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI. N is the value in PMCFGR.N.

Possible values of each bit are:

`0` When read, means that PMEVCNTR<x> has not overflowed. When written, has no effect.

`1` When read, means that PMEVCNTR<x> has overflowed. When written, clears the PMEVCNTR<x> overflow bit to 0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the PMOVSCLR_EL0:

PMOVSCLR_EL0 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xC80

Non-Confidential - Beta

I3.3.26 PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set register

The PMOVSSET_EL0 characteristics are:

Purpose

Sets the state of the overflow bit for the Cycle Count Register, PMCCNTR_EL0, and each of the implemented event counters PMEVCNTR<x>.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMOVSSET_EL0 is architecturally mapped to AArch64 System register PMOVSSET_EL0.

External register PMOVSSET_EL0 is architecturally mapped to AArch32 System register PMOVSSET.

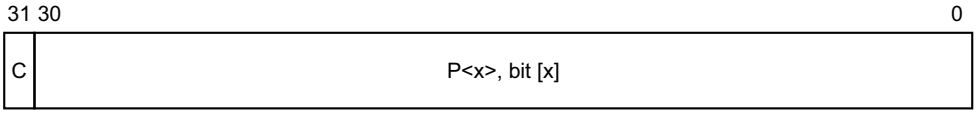
PMOVSSET_EL0 is in the Core power domain.

Attributes

PMOVSSET_EL0 is a 32-bit register.

Field descriptions

The PMOVSSET_EL0 bit assignments are:



C, bit [31]

PMCCNTR_EL0 overflow bit. Possible values are:

`0` When read, means the cycle counter has not overflowed. When written, has no effect.

`1` When read, means the cycle counter has overflowed. When written, sets the overflow bit to 1.

P<x>, bit [x], for x = 0 to 30

Event counter overflow set bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI. N is the value in PMCFGR.N.

Possible values are:

`0` When read, means that PMEVCNTR<x> has not overflowed. When written, has no effect.

`1` When read, means that PMEVCNTR<x> has overflowed. When written, sets the PMEVCNTR<x> overflow bit to 1.

I3.3.27 PMPIDR0, Performance Monitors Peripheral Identification Register 0

The PMPIDR0 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMPIDR0 is in the Debug power domain.

PMPIDR0 is optional to implement in the external register interface.

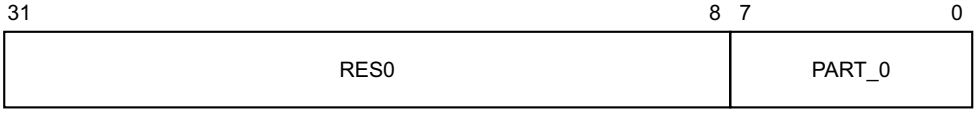
This register is required for CoreSight compliance.

Attributes

PMPIDR0 is a 32-bit register.

Field descriptions

The PMPIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PART_0, bits [7:0]

Part number, least significant byte.

Accessing the PMPIDR0:

PMPIDR0 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFE0

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.28 PMPIDR1, Performance Monitors Peripheral Identification Register 1

The PMPIDR1 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMPIDR1 is in the Debug power domain.

PMPIDR1 is optional to implement in the external register interface.

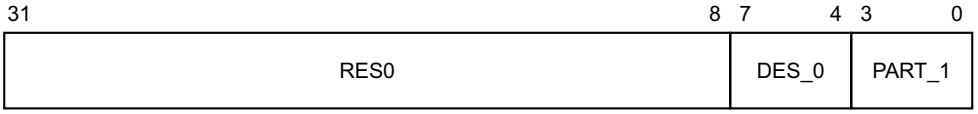
This register is required for CoreSight compliance.

Attributes

PMPIDR1 is a 32-bit register.

Field descriptions

The PMPIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

DES_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is `0b1011`.

PART_1, bits [3:0]

Part number, most significant nibble.

Accessing the PMPIDR1:

PMPIDR1 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xFE4`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.29 PMPIDR2, Performance Monitors Peripheral Identification Register 2

The PMPIDR2 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMPIDR2 is in the Debug power domain.

PMPIDR2 is optional to implement in the external register interface.

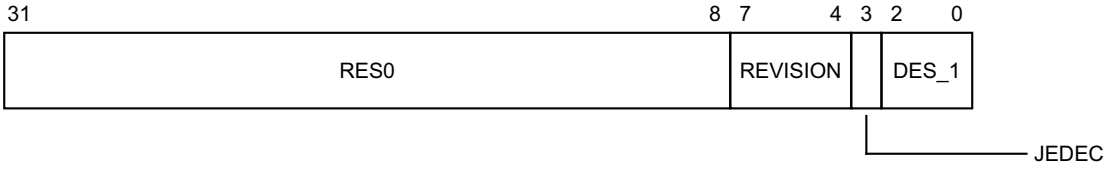
This register is required for CoreSight compliance.

Attributes

PMPIDR2 is a 32-bit register.

Field descriptions

The PMPIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

JEDEC, bit [3]

RAO. Indicates a JEP106 identity code is used.

DES_1, bits [2:0]

Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is `0b011`.

Accessing the PMPIDR2:

PMPIDR2 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xFE8`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.30 PMPIDR3, Performance Monitors Peripheral Identification Register 3

The PMPIDR3 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMPIDR3 is in the Debug power domain.

PMPIDR3 is optional to implement in the external register interface.

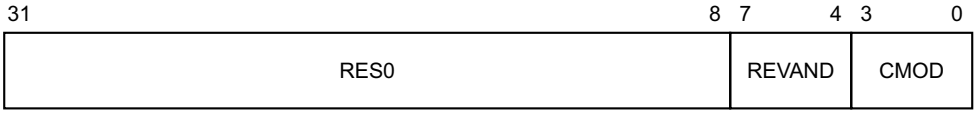
This register is required for CoreSight compliance.

Attributes

PMPIDR3 is a 32-bit register.

Field descriptions

The PMPIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVAND, bits [7:4]

Part minor revision. Parts using PMPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.

CMOD, bits [3:0]

Customer modified. Indicates someone other than the Designer has modified the component.

Accessing the PMPIDR3:

PMPIDR3 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFEC

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.31 PMPIDR4, Performance Monitors Peripheral Identification Register 4

The PMPIDR4 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMPIDR4 is in the Debug power domain.

PMPIDR4 is optional to implement in the external register interface.

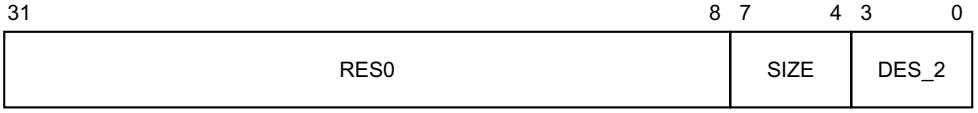
This register is required for CoreSight compliance.

Attributes

PMPIDR4 is a 32-bit register.

Field descriptions

The PMPIDR4 bit assignments are:



Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. RAZ. Log_2 of the number of 4KB pages from the start of the component to the end of the component ID registers.

DES_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is `0b0100`.

Accessing the PMPIDR4:

PMPIDR4 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xFD0`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.3.32 PMSWINC_EL0, Performance Monitors Software Increment register

The PMSWINC_EL0 characteristics are:

Purpose

Increments a counter that is configured to count the Software increment event, event `0x00`.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	WI	WO

Configurations

External register PMSWINC_EL0 is architecturally mapped to AArch64 System register PMSWINC_EL0.

External register PMSWINC_EL0 is architecturally mapped to AArch32 System register PMSWINC.

PMSWINC_EL0 is in the Core power domain.

PMSWINC_EL0 is optional to implement in the external register interface.

If this register is implemented, use of it is deprecated.

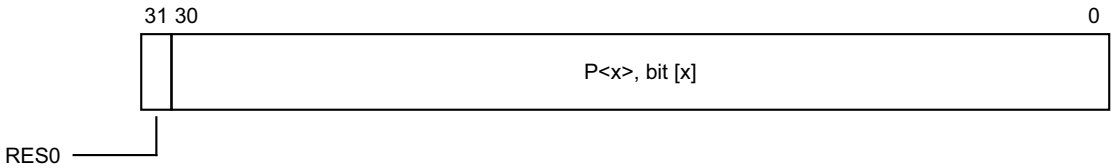
If 1 is written to bit [x] from the external debug interface, it is CONSTRAINED UNPREDICTABLE whether or not a SW_INCR event is created for counter x. This is consistent with not implementing the register in the external debug interface.

Attributes

PMSWINC_EL0 is a 32-bit register.

Field descriptions

The PMSWINC_EL0 bit assignments are:



Bit [31]

Reserved, RES0.

P<x>, bit [x], for x = 0 to 30

Event counter software increment bit for PMEVCNTR<x>.

P<x> is WI if x >= PMCR_EL0.N, the number of implemented counters.

Otherwise, the effects of writing to this bit are:

`0` No action. The write to this bit is ignored.

`1` It is CONSTRAINED UNPREDICTABLE whether a SW_INCR event is generated for event counter x.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the PMSWINC_EL0:

PMSWINC_EL0 can be accessed through the memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xCA0

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.4 Generic Timer memory-mapped registers overview

The Generic Timer memory-mapped registers are implemented as multiple register frames, with each register frame having its own base address, as follows:

- A single CNTCTLBase register frame, at base address CNTCTLBase.
- Between one and seven CNTBase*N* register frames, each with its own base address CNTBase*N*.
- For each CNTBase*N* register frame, if required, a CNTEL0Base*N* register frame, at base address CNTEL0Base*N*, that provides an EL0 view of the CNTBase*N* register frame.

For more information, see:

- *Memory-mapped timer components* on page I1-4969.
- *The CNTBaseN and CNTEL0BaseN frames* on page I1-4970. This section includes the memory map of the CNTBase*N* and CNTBase*N* register frames.
- *The CNTCTLBase frame* on page I1-4969. This section includes the memory map of the CNTCTLBase register frame.
- *Providing a complete set of counter and timer features* on page I1-4973.

Non-Confidential - Beta

I3.5 Generic Timer memory-mapped register descriptions

This section describes the Generic Timer registers. *Generic Timer memory-mapped registers overview* on page I3-5037 gives an overview of these registers, and includes links to their memory maps.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.5.1 CNTACR<n>, Counter-timer Access Control Registers, n = 0 - 7

The CNTACR<n> characteristics are:

Purpose

Provides top-level access controls for the elements of a timer frame. CNTACR<n> provides the controls for frame CNTBaseN.

In addition to the CNTACR<n> control:

- CNTNSAR controls whether CNTACR<n> is accessible by Non-secure accesses.
- If frame CNTEL0BaseN is implemented, the CNTEL0ACR in frame CNTBaseN provides additional control of accesses to frame CNTEL0BaseN.

Usage constraints

This register is accessible as follows:

Default
RW

In a system that implements both Secure and Non-secure states:

- CNTACR<n> is always accessible by Secure accesses.
- CNTNSAR.NS<n> determines whether CNTACR<n> is accessible by Non-secure accesses.

Configurations

Implemented only if the value of CNTTIDR.Frame<n> is 1.

An implementation of the counters might not provide configurable access to some or all of the features. In this case, the associated field in the CNTACR<n> register is:

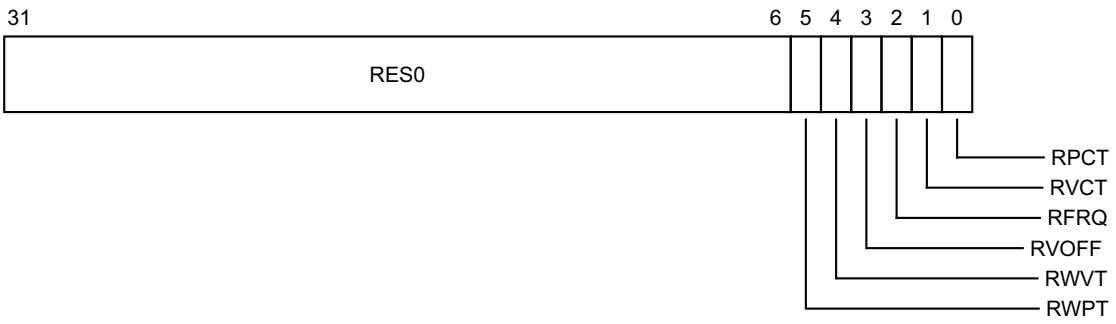
- RAZ/WI if access is always denied.
- RAO/WI if access is always permitted.

Attributes

CNTACR<n> is a 32-bit register.

Field descriptions

The CNTACR<n> bit assignments are:



Bits [31:6]

Reserved, RES0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

RWPT, bit [5]

Read/write access to the EL1 Physical Timer registers CNTP_CVAL, CNTP_TVAL, and CNTP_CTL, in frame <n>. The possible values of this bit are:

`0` No access to the EL1 Physical Timer registers in frame <n>. The registers are RES0.

`1` Read/write access to the EL1 Physical Timer registers in frame <n>.

RWVT, bit [4]

Read/write access to the Virtual Timer register CNTV_CVAL, CNTV_TVAL, and CNTV_CTL, in frame <n>. The possible values of this bit are:

`0` No access to the Virtual Timer registers in frame <n>. The registers are RES0.

`1` Read/write access to the Virtual Timer registers in frame <n>.

RVOFF, bit [3]

Read-only access to CNTVOFF, in frame <n>. The possible values of this bit are:

`0` No access to CNTVOFF in frame <n>. The register is RES0.

`1` Read-only access to CNTVOFF in frame <n>.

RFRQ, bit [2]

Read-only access to CNTFRQ, in frame <n>. The possible values of this bit are:

`0` No access to CNTFRQ in frame <n>. The register is RES0.

`1` Read-only access to CNTFRQ in frame <n>.

RVCT, bit [1]

Read-only access to CNTVCT, in frame <n>. The possible values of this bit are:

`0` No access to CNTVCT in frame <n>. The register is RES0.

`1` Read-only access to CNTVCT in frame <n>.

RPCT, bit [0]

Read-only access to CNTPCT, in frame <n>. The possible values of this bit are:

`0` No access to CNTPCT in frame <n>. The register is RES0.

`1` Read-only access to CNTPCT in frame <n>.

Accessing the CNTACR<n>:

CNTACR<n> can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTCTLBase	`0x040` + 4n

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.5.2 CNTCR, Counter Control Register

The CNTCR characteristics are:

Purpose

Enables the counter, controls the counter frequency setting, and controls counter behavior during debug.

Usage constraints

This register is accessible as follows:

Default
RW

In a system that implements both Secure and Non-secure states, this register is only writable by Secure accesses.

Configurations

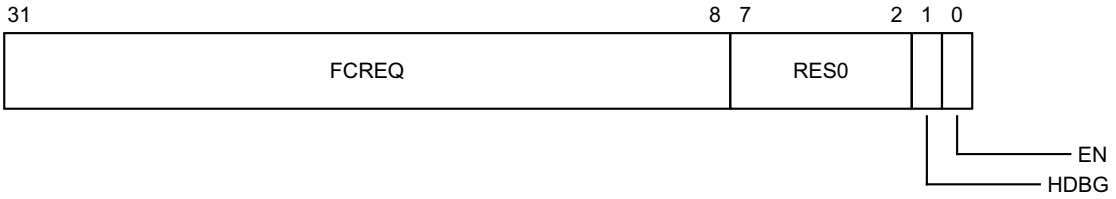
There are no configuration notes.

Attributes

CNTCR is a 32-bit register.

Field descriptions

The CNTCR bit assignments are:



FCREQ, bits [31:8]

Frequency change request. Indicates the number of the entry in the frequency table to select.

Selecting an unimplemented entry, or an entry that contains 0, has no effect on the counter.

When this register has an architecturally-defined reset value, this field resets to `0`.

Bits [7:2]

Reserved, RES0.

HDBG, bit [1]

Halt-on-debug. Controls whether a Halt-on-debug signal halts the system counter:

`0` System counter ignores Halt-on-debug.

`1` Asserted Halt-on-debug signal halts system counter update.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

EN, bit [0]

Enables the counter:

`0` System counter disabled.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

1 System counter enabled.

When this register has an architecturally-defined reset value, this field resets to `0`.

Accessing the CNTCR:

CNTCR can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	`0x000`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.5.3 CNTCV, Counter Count Value register

The CNTCV characteristics are:

Purpose

Indicates the current count value.

Usage constraints

This register is accessible as follows:

Frame	Accessibility
CNTControlBase	RW
CNTReadBase	RO

A write to CNTCV must be visible in the CNTPCT register of each running processor in a finite time.

For the writable copy of the register:

- If the counter is enabled, the effect if writing the register is UNPREDICTABLE.
- If the system implements both Secure and Non-secure states, the register is writable only by Secure writes.

In an implementation that supports 64-bit atomic memory accesses, this register must be accessible using a 64-bit atomic access.

Configurations

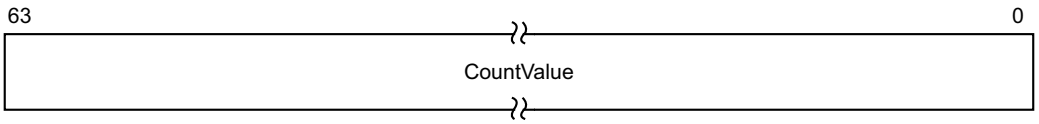
There are no configuration notes.

Attributes

CNTCV is a 64-bit register.

Field descriptions

The CNTCV bit assignments are:



CountValue, bits [63:0]

Indicates the counter value.

Accessing the CNTCV:

CNTCV[31:0] can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x008
Timer	CNTReadBase	0x000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

CNTCV[63:32] can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x00C
Timer	CNTReadBase	0x004

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.5.4 CNTEL0ACR, Counter-timer EL0 Access Control Register

The CNTEL0ACR characteristics are:

Purpose

An implementation of CNTEL0ACR in the frame at CNTBaseN controls whether the CNTPCT, CNTVCT, CNTFRQ, EL1 Physical Timer, and Virtual Timer registers are visible in the frame at CNTEL0BaseN.

Usage constraints

This register is accessible as follows:

Default
RW

If CNTEL0ACR is implemented, it is implemented as a RW register in the CNTBaseN frame when the value of bit[0] of CNTTIDR.Frame<n> is 1, otherwise the encoding is RES0.

If CNTEL0ACR is not implemented:

- The register location is RAZ/WI.
- The registers CNTFRQ, CNTP_CTL, CNTP_CVAL, CNTP_TVAL, CNTPCT, CNTV_CTL, CNTV_CVAL, CNTV_TVAL, and CNTVCT are not visible in the corresponding CNTEL0BaseN frame.

Configurations

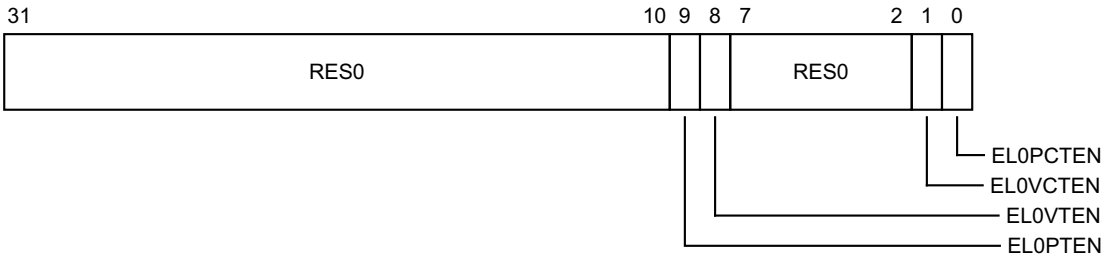
CNTEL0ACR is optional to implement in the external register interface.

Attributes

CNTEL0ACR is a 32-bit register.

Field descriptions

The CNTEL0ACR bit assignments are:



Bits [31:10]

Reserved, RES0.

EL0PTEN, bit [9]

Second view read/write access control for the EL1 Physical Timer registers. This bit controls whether the CNTP_CVAL, CNTP_TVAL, and CNTP_CTL registers in the current CNTBaseN frame are also accessible in the corresponding CNTEL0BaseN frame. The possible values of this bit are:

`0` No access. Registers are RES0 in the second view.

`1` Access permitted. If the registers are accessible in the current frame then they are accessible in the second view.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

EL0VTEN, bit [8]

Second view read/write access control for the Virtual Timer registers. This bit controls whether the CNTV_CVAL, CNTV_TVAL, and CNTV_CTL registers in the current CNTBaseN frame are also accessible in the corresponding CNTEL0BaseN frame. The possible values of this bit are:

`0` No access. Registers are RES0 in the second view.

`1` Access permitted. If the registers are accessible in the current frame then they are accessible in the second view.

The definition of this bit means that, if the Virtual Timer registers are not implemented in the current CNTBaseN frame, then the Virtual Timer register addresses are RES0 in the corresponding CNTEL0BaseN frame, regardless of the value of this bit.

Bits [7:2]

Reserved, RES0.

EL0VCTEN, bit [1]

Second view read access control for CNTVCT and CNTFRQ. The possible values of this bit are:

`0` CNTVCT is not visible in the second view.
If EL0PCTEN is set to 0, CNTFRQ is not visible in the second view.

`1` Access permitted. If CNTVCT and CNTFRQ are visible in the current frame then they are visible in the second view.

EL0PCTEN, bit [0]

Second view read access control for CNTPCT and CNTFRQ. The possible values of this bit are:

`0` CNTPCT is not visible in the second view.
If EL0VCTEN is set to 0, CNTFRQ is not visible in the second view.

`1` Access permitted. If CNTPCT and CNTFRQ are visible in the current frame then they are visible in the second view.

Accessing the CNTEL0ACR:

CNTEL0ACR can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	`0x014`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.5.5 CNTFID0, Counter Frequency ID

The CNTFID0 characteristics are:

Purpose

Indicates the base frequency of the system counter.

Usage constraints

This register is accessible as follows:

Default
RO or RW

Configurations

The possible frequencies for the system counter are stored as 32-bit words starting with the base frequency, CNTFID0.

A 32-bit word of zero value after the final frequency mode entry marks the end of the frequency modes table.

Typically, the frequency modes table will be in read-only memory. However, a system implementation might use read/write memory for the table, and initialize the table entries as part of its start-up sequence.

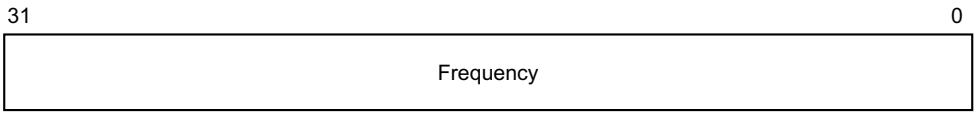
If the frequency modes table is in read/write memory, ARM strongly recommends that the frequency modes table is not updated once the system is running.

Attributes

CNTFID0 is a 32-bit register.

Field descriptions

The CNTFID0 bit assignments are:



Frequency, bits [31:0]

The base frequency of the system counter, in Hz.

Accessing the CNTFID0:

CNTFID0 can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x020

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.5.6 CNTFID<n>, Counter Frequency IDs, n = 1 - 23

The CNTFID<n> characteristics are:

Purpose

Indicates alternative system counter update frequencies.

Usage constraints

This register is accessible as follows:

Default
RO or RW

Configurations

CNTFID<n> is optional to implement in the external register interface.

The possible frequencies for the system counter are stored as 32-bit words starting with the base frequency, CNTFID0.

A 32-bit word of zero value after the final frequency mode entry marks the end of the frequency modes table. The only required entry in the table is the entry for CNTFID0.

Typically, the frequency modes table will be in read-only memory. However, a system implementation might use read/write memory for the table, and initialise the table entries as part of its start-up sequence.

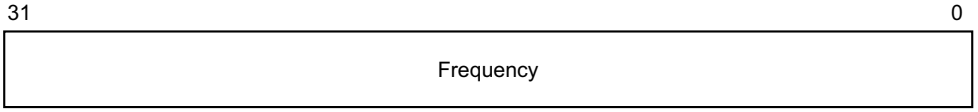
If the frequency modes table is in read/write memory, ARM strongly recommends that the frequency modes table is not updated once the system is running.

Attributes

CNTFID<n> is a 32-bit register.

Field descriptions

The CNTFID<n> bit assignments are:



Frequency, bits [31:0]

A system counter update frequency, in Hz. Must be an exact divisor of the base frequency. ARM strongly recommends that all frequency values in the table are integer power-of-two divisors of the base frequency.

When the system timer is operating at a lower frequency than the base frequency, the increment applied at each counter update is given by:

increment = (base frequency) / selected frequency)

Accessing the CNTFID<n>:

CNTFID<n> can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	`0x020` + 4n

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.5.7 CNTFRQ, Counter-timer Frequency

The CNTFRQ characteristics are:

Purpose

This register is provided so that software can discover the frequency of the system counter. It must be programmed with this value as part of system initialization. The value of the register is not interpreted by hardware.

Usage constraints

This register is accessible as follows:

Frame	Accessibility
CNTCTLBase	RW
CNTBaseN	Config-RO
CNTEL0BaseN	Config-RO

For the CNTBaseN and CNTEL0BaseN frames:

- A RO copy of CNTFRQ is implemented in the CNTBaseN frame when both:
  - CNTACR<n>.RFRQ is 1.
  - Bit[0] of CNTTIDR.Frame<n> is 1.

  Otherwise the encoding in CNTBaseN is RES0.
- When CNTFRQ is RO in the CNTBaseN frame, it is also RO in the CNTEL0BaseN frame if bit[2] of CNTTIDR.Frame<n> is 1 and either:
  - The value of CNTEL0ACR.EL0VCTEN is 1.
  - The value of CNTEL0ACR.EL0PCTEN is 1.

  Otherwise the CNTFRQ encoding in CNTEL0BaseN frame is RES0.

In a system that implements both Secure and Non-secure states, this register is only accessible by Secure accesses.

Configurations

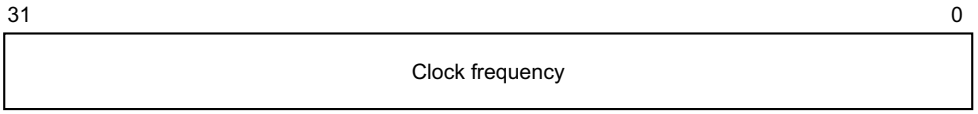
There are no configuration notes.

Attributes

CNTFRQ is a 32-bit register.

Field descriptions

The CNTFRQ bit assignments are:



Bits [31:0]

Clock frequency. Indicates the system counter clock frequency, in Hz.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the CNTFRQ:

CNTFRQ can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x010
Timer	CNTEL0BaseN	0x010
Timer	CNTCTLBase	0x000

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.5.8 CNTNSAR, Counter-timer Non-secure Access Register

The CNTNSAR characteristics are:

Purpose

Provides the highest-level control of whether frames CNTBaseN and CNTEL0BaseN are accessible by Non-secure accesses.

Usage constraints

This register is accessible as follows:

Default
RW

In a system that implements both Secure and Non-secure states, this register is only accessible by Secure accesses.

Configurations

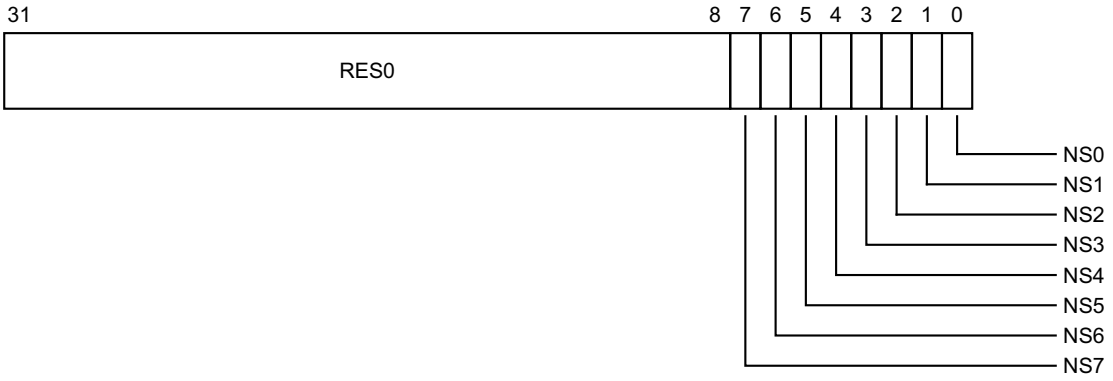
There are no configuration notes.

Attributes

CNTNSAR is a 32-bit register.

Field descriptions

The CNTNSAR bit assignments are:



Bits [31:8]

Reserved, RES0.

NS<n>, bit [n], for n = 0 to 7

Non-secure access to frame n. The possible values of this bit are:

0 Secure access only. Behaves as RES0 to Non-secure accesses.

1 Secure and Non-secure accesses permitted.

This bit also determines whether, in the CNTCTLBase frame, CNTACR<n> and CNTVOFF<n> are accessible to Non-secure accesses.

If frame CNTBase<n>:

- Is not implemented, then NS<n> is RES0.
- Is not Configurable access, and is accessible only by Secure accesses, then NS<n> is RES0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- Is not Configurable access, and is accessible by both Secure and Non-secure accesses, then NS<n> is RES1.

Accessing the CNTNSAR:

CNTNSAR can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTCTLBase	0x004

I3.5.9 CNTP_CTL, Counter-timer Physical Timer Control

The CNTP_CTL characteristics are:

Purpose

Control register for the physical timer.

Usage constraints

This register is accessible as follows:

Frame	Accessibility
CNTBaseN	Config-RW
CNTEL0BaseN	Config-RW

CNTP_CTL is implemented as a RW register in the CNTBaseN frame when both:

- The value of CNTACR<n>.RWPT is 1.
- Bit[0] of CNTTIDR.Frame<n> is 1.

Otherwise the encoding in the CNTBaseN frame is RES0.

When CNTP_CTL is implemented as a RW register in the CNTBaseN frame, it is also implemented as a RW register in the CNTEL0BaseN frame if both.

- The value of CNTEL0ACR.EL0PTEN is 1.
- Bit[2] of CNTTIDR.Frame<n> is 1.

Otherwise the CNTP_CTL register in the CNTEL0BaseN frame is RES0.

Configurations

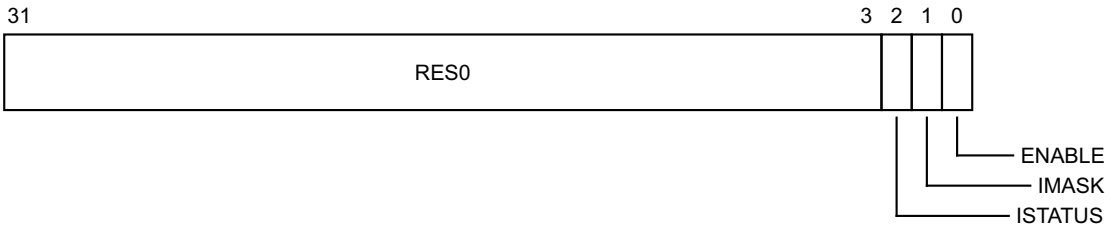
There are no configuration notes.

Attributes

CNTP_CTL is a 32-bit register.

Field descriptions

The CNTP_CTL bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is asserted:

0 Timer condition is not asserted.

1 Timer condition is asserted.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer value meets the condition for the timer output to be asserted. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer output signal is asserted.

For more information see *Operation of the CompareValue views of the timers* on page D6-1798 and *Operation of the TimerValue views of the timers* on page D6-1799.

This bit is read-only.

IMASK, bit [1]

Timer output signal mask bit. Permitted values are:

`0` Timer output signal is not masked.

`1` Timer output signal is masked.

For more information, see the description of the ISTATUS bit.

ENABLE, bit [0]

Enables the timer. Permitted values are:

`0` Timer disabled.

`1` Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTP_TVAL continues to count down.

Note

Disabling the output signal might be a power-saving option.

Accessing the CNTP_CTL:

CNTP_CTL can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	`0x02C`
Timer	CNTEL0BaseN	`0x02C`

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.5.10 CNTP_CVAL, Counter-timer Physical Timer CompareValue

The CNTP_CVAL characteristics are:

Purpose

Holds the 64-bit compare value for the EL1 physical timer.

Usage constraints

This register is accessible as follows:

Frame	Accessibility
CNTBaseN	Config-RW
CNTEL0BaseN	Config-RW

CNTP_CVAL is implemented as a RW register in the CNTBaseN frame when both:

- The value of CNTACR<n>.RWPT is 1.
- Bit[0] of CNTTIDR.Frame<n> is 1.

Otherwise the encoding in the CNTBaseN frame is RES0.

When CNTP_CVAL is implemented as a RW register in the CNTBaseN frame, it is also implemented as a RW register in the CNTEL0BaseN frame if both:

- The value of CNTEL0ACR.EL0PTEN is 1.
- Bit[2] of CNTTIDR.Frame<n> is 1.

Otherwise the CNTP_CVAL register in the CNTEL0BaseN frame is RES0.

If the implementation supports 64-bit atomic accesses, then the CNTP_CVAL register must be accessible as an atomic 64-bit value.

Configurations

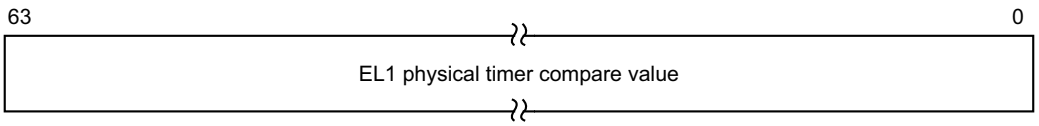
There are no configuration notes.

Attributes

CNTP_CVAL is a 64-bit register.

Field descriptions

The CNTP_CVAL bit assignments are:



Bits [63:0]

EL1 physical timer compare value.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the CNTP_CVAL:

CNTP_CVAL[31:0] can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x020
Timer	CNTEL0BaseN	0x020

CNTP_CVAL[63:32] can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x024
Timer	CNTEL0BaseN	0x024

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.5.11 CNTP_TVAL, Counter-timer Physical Timer TimerValue

The CNTP_TVAL characteristics are:

Purpose

Holds the timer value for the EL1 physical timer. This provides a 32-bit downcounter.

Usage constraints

This register is accessible as follows:

Frame	Accessibility
CNTBaseN	Config-RW
CNTEL0BaseN	Config-RW

CNTP_TVAL is implemented as a RW register in the CNTBaseN frame when both:

- The value of CNTACR<n>.RWPT is 1.
- Bit[0] of CNTTIDR.Frame<n> is 1.

Otherwise the encoding in the CNTBaseN frame is RES0.

When CNTP_TVAL is implemented as a RW register in the CNTBaseN frame, it is also implemented as RW in the CNTEL0BaseN frame if both:

- The value of CNTEL0ACR.EL0PTEN is 1.
- Bit[2] of CNTTIDR.Frame<n> is 1.

Otherwise the CNTP_TVAL register in the CNTEL0BaseN frame is RES0.

Configurations

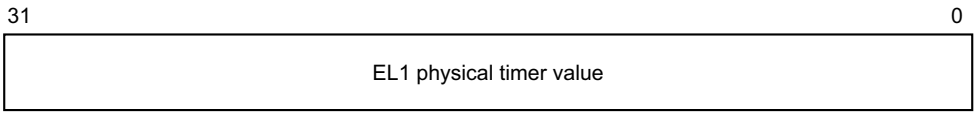
There are no configuration notes.

Attributes

CNTP_TVAL is a 32-bit register.

Field descriptions

The CNTP_TVAL bit assignments are:



Bits [31:0]

EL1 physical timer value.

Accessing the CNTP_TVAL:

CNTP_TVAL can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x028
Timer	CNTEL0BaseN	0x028

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.5.12 CNTPCT, Counter-timer Physical Count

The CNTPCT characteristics are:

Purpose

Holds the 64-bit physical count value.

Usage constraints

This register is accessible as follows:

Frame	Accessibility
CNTBaseN	Config-RO
CNTEL0BaseN	Config-RO

CNTPCT is implemented as a RO register in the CNTBaseN frame when both:

- The value of CNTACR<n>.RPCT is 1.
- Bit[0] of CNTTIDR.Frame<n> is 1.

Otherwise the encoding in the CNTBaseN frame is RES0.

When CNTPCT is implemented as a RO register in the CNTBaseN frame, it is also implemented as a RO register in the CNTEL0BaseN frame if both:

- The value of CNTEL0ACR.EL0PCTEN is 1.
- Bit[2] of CNTTIDR.Frame<n> is 1.

Otherwise the CNTPCT register in the CNTEL0BaseN frame is RES0.

If the implementation supports 64-bit atomic accesses, then the CNTPCT register must be accessible as an atomic 64-bit value.

Configurations

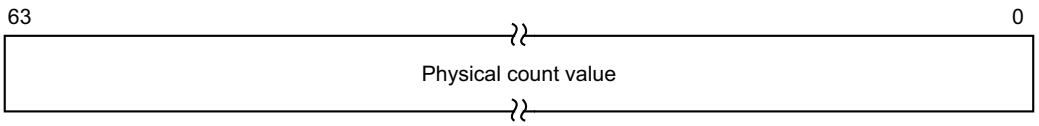
There are no configuration notes.

Attributes

CNTPCT is a 64-bit register.

Field descriptions

The CNTPCT bit assignments are:



Bits [63:0]

Physical count value.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the CNTPCT:

CNTPCT[31:0] can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x000
Timer	CNTEL0BaseN	0x000

CNTPCT[63:32] can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x004
Timer	CNTEL0BaseN	0x004

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.5.13 CNTSR, Counter Status Register

The CNTSR characteristics are:

Purpose

Provides counter frequency status information.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

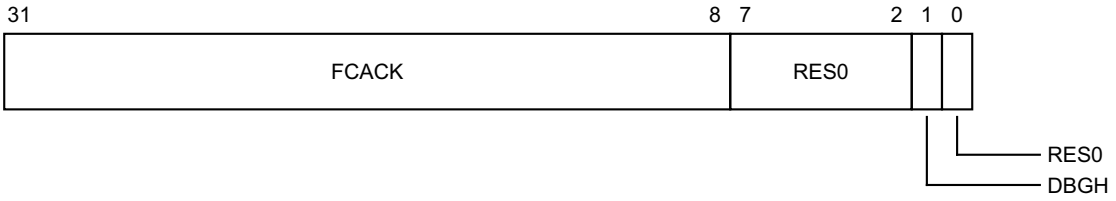
There are no configuration notes.

Attributes

CNTSR is a 32-bit register.

Field descriptions

The CNTSR bit assignments are:



FCACK, bits [31:8]

Frequency change acknowledge. Indicates the currently selected entry in the frequency table.

When this register has an architecturally-defined reset value, this field resets to `0`.

Bits [7:2]

Reserved, RES0.

DBGH, bit [1]

Indicates whether the counter is halted because the Halt-on-Debug signal is asserted:

`0` Counter is not halted.

`1` Counter is halted.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bit [0]

Reserved, RES0.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the CNTSR:

CNTSR can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x004

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.5.14 CNTTIDR, Counter-timer Timer ID Register

The CNTTIDR characteristics are:

Purpose

Indicates the implemented timers in the memory map, and their features. For each value of N from 0 to 7 it indicates whether:

- Frame CNTBaseN is a view of an implemented timer.
- Frame CNTBaseN has a second view, CNTEL0BaseN.
- Frame CNTBaseN has a virtual timer capability.

Usage constraints

This register is accessible as follows:

Default
RO

This register is accessible by both Secure and Non-secure accesses.

Configurations

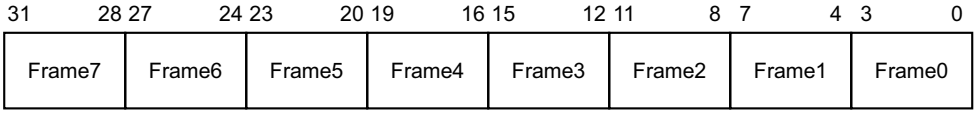
There are no configuration notes.

Attributes

CNTTIDR is a 32-bit register.

Field descriptions

The CNTTIDR bit assignments are:



Frame<n>, bits [4n+3:4n], for n = 0 to 7

A 4-bit field indicating the features of frame CNTBase<n>.

Bit[3] of the field is RES0.

Bit[2] indicates whether frame CNTBase<n> has a second view, CNTEL0Base<n>. The possible values of this bit are:

Bit[2]	Meaning
0	Frame <n> does not have a second view. CNTEL0Base<n> is RES0.
1	Frame <n> has a second view, CNTEL0Base<n>.

If bit[0] is 0, bit[2] is RES0.

Bit[1] indicates whether both:

- Frame CNTBase<n> implements the virtual timer registers CNTV_CVAL, CNTV_TVAL, and CNTV_CTL.
- This CNTCTLBase frame implements the virtual timer offset register CNTVOFF<n>.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

The possible values of bit[1] are:

Bit[1]	Meaning
0	Frame <n> does not have virtual capability. The virtual time and offset registers are RES0.
1	Frame <n> has virtual capability. The virtual time and offset registers are implemented.

If bit[0] is 0, bit[1] is RES0.

Bit[0] indicates whether frame CNTBase<n> is implemented. The possible values of this bit are:

Bit[0]	Meaning
0	Frame <n> not implemented. All registers associated with the frame are RES0.
1	Frame <n> is implemented.

Accessing the CNTTIDR:

CNTTIDR can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTCTLBase	0x008

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.5.15 CNTV_CTL, Counter-timer Virtual Timer Control

The CNTV_CTL characteristics are:

Purpose

Control register for the virtual timer.

Usage constraints

This register is accessible as follows:

Frame	Accessibility
CNTBaseN	Config-RW
CNTEL0BaseN	Config-RW

If CNTV_CTL is implemented, it is implemented as a RW register in the CNTBaseN frame when both:

- The value of CNTACR<n>.RWVT is 1.
- Bits[1:0] of CNTTIDR.Frame<n> are 1.

Otherwise the encoding in the CNTBaseN frame is RES0.

When CNTV_CTL is implemented as a RW register in the CNTBaseN frame, it is also implemented as a RW register in the CNTEL0BaseN frame if both:

- The value of CNTEL0ACR.EL0VTEN is 1.
- Bit[2] of CNTTIDR.Frame<n> is 1.

Otherwise the CNTV_CTL register in the CNTEL0BaseN frame is RES0.

If CNTV_CTL is not implemented, the register location is RAZ/WI.

Configurations

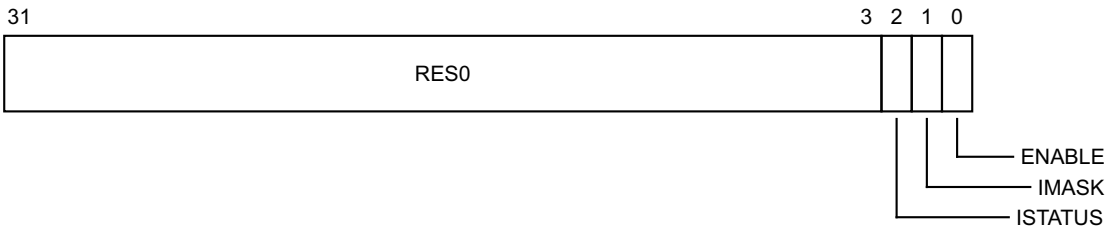
CNTV_CTL is optional to implement in the external register interface.

Attributes

CNTV_CTL is a 32-bit register.

Field descriptions

The CNTV_CTL bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is asserted:

`0` Timer condition is not asserted.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

1 Timer condition is asserted.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer value meets the condition for the timer output to be asserted. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer output signal is asserted.

For more information see *Operation of the CompareValue views of the timers* on page D6-1798 and *Operation of the TimerValue views of the timers* on page D6-1799.

This bit is read-only.

IMASK, bit [1]

Timer output signal mask bit. Permitted values are:

0 Timer output signal is not masked.

1 Timer output signal is masked.

For more information, see the description of the ISTATUS bit.

ENABLE, bit [0]

Enables the timer. Permitted values are:

0 Timer disabled.

1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTV_TVAL continues to count down.

Note

Disabling the output signal might be a power-saving option.

Accessing the CNTV_CTL:

CNTV_CTL can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x03C
Timer	CNTEL0BaseN	0x03C

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.5.16 CNTV_CVAL, Counter-timer Virtual Timer CompareValue

The CNTV_CVAL characteristics are:

Purpose

Holds the 64-bit compare value for the virtual timer.

Usage constraints

This register is accessible as follows:

Frame	Accessibility
CNTBaseN	Config-RW
CNTEL0BaseN	Config-RW

If CNTV_CVAL is implemented, it is implemented as a RW register in the CNTBaseN frame when both:

- The value of CNTACR<n>.RWVT is 1.
- Bits[1:0] of CNTTIDR.Frame<n> are 1.

Otherwise the encoding in the CNTBaseN frame is RES0.

When CNTV_CVAL is implemented as a RW register in the CNTBaseN frame, it is also implemented as a RW register in the CNTEL0BaseN frame if both.

- The value of CNTEL0ACR.EL0VTEN is 1.
- Bit[2] of CNTTIDR.Frame<n> is 1.

Otherwise the CNTV_CVAL register in the CNTEL0BaseN frame is RES0.

If CNTV_CVAL is not implemented, the register location is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTV_CVAL register must be accessible as an atomic 64-bit value.

Configurations

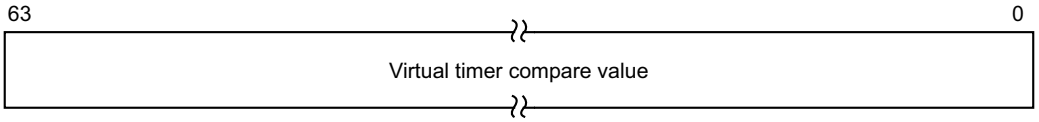
CNTV_CVAL is optional to implement in the external register interface.

Attributes

CNTV_CVAL is a 64-bit register.

Field descriptions

The CNTV_CVAL bit assignments are:



Bits [63:0]

Virtual timer compare value.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the CNTV_CVAL:

CNTV_CVAL[31:0] can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x030
Timer	CNTEL0BaseN	0x030

CNTV_CVAL[63:32] can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x034
Timer	CNTEL0BaseN	0x034

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.5.17 CNTV_TVAL, Counter-timer Virtual Timer TimerValue

The CNTV_TVAL characteristics are:

Purpose

Holds the timer value for the virtual timer.

Usage constraints

This register is accessible as follows:

Frame	Accessibility
CNTBaseN	Config-RW
CNTEL0BaseN	Config-RW

If CNTV_TVAL is implemented, it is implemented as a RW register in the CNTBaseN frame when both:

- The value of CNTACR<n>.RWVT is 1.
- Bits[1:0] of CNTTIDR.Frame<n> are 1.

Otherwise the encoding in the CNTBaseN frame is RES0.

When CNTV_TVAL is implemented as a RW register in the CNTBaseN frame, it is also implemented as RW in the CNTEL0BaseN frame if both:

- The value of CNTEL0ACR.EL0VTEN is 1.
- Bit[2] of CNTTIDR.Frame<n> is 1.

Otherwise the CNTV_TVAL register in the CNTEL0BaseN frame is RES0.

If CNTV_TVAL is not implemented, the register location is RAZ/WI.

Configurations

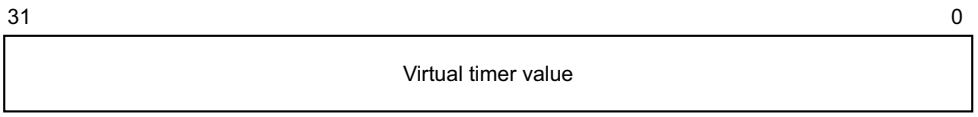
CNTV_TVAL is optional to implement in the external register interface.

Attributes

CNTV_TVAL is a 32-bit register.

Field descriptions

The CNTV_TVAL bit assignments are:



Bits [31:0]

Virtual timer value.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the CNTV_TVAL:

CNTV_TVAL can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x038
Timer	CNTEL0BaseN	0x038

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.5.18 CNTVCT, Counter-timer Virtual Count

The CNTVCT characteristics are:

Purpose

Holds the 64-bit virtual count value.

Usage constraints

This register is accessible as follows:

Frame	Accessibility
CNTBaseN	Config-RO
CNTEL0BaseN	Config-RO

CNTVCT is implemented as a RO register in the CNTBaseN frame when both:

- The value of CNTACR<n>.RVCT is 1.
- Bit[0] of CNTTIDR.Frame<n> is 1.

Otherwise the encoding in the CNTBaseN frame is RES0.

When CNTVCT is implemented as a RO register in the CNTBaseN frame, it is also implemented as a RO register in the CNTEL0BaseN frame if both:

- The value of CNTEL0ACR.EL0VCTEN is 1.
- Bit[2] of CNTTIDR.Frame<n> is 1.

Otherwise the CNTVCT register in the CNTEL0BaseN frame is RES0.

If the implementation supports 64-bit atomic accesses, then the CNTVCT register must be accessible as an atomic 64-bit value.

Configurations

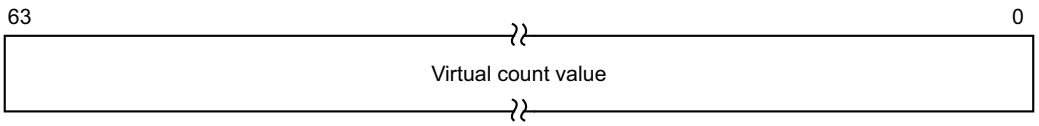
There are no configuration notes.

Attributes

CNTVCT is a 64-bit register.

Field descriptions

The CNTVCT bit assignments are:



Bits [63:0]

Virtual count value.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Accessing the CNTVCT:

CNTVCT[31:0] can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x008
Timer	CNTEL0BaseN	0x008

CNTVCT[63:32] can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x00C
Timer	CNTEL0BaseN	0x00C

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.5.19 CNTVOFF{<n>}, Counter-timer Virtual Offset

The CNTVOFF{<n>} characteristics are:

Purpose

Holds the 64-bit virtual offset.

Usage constraints

This register is accessible as follows:

Frame	Mnemonic	Accessibility
CNTCTLBase	CNTVOFF<n>, n = 1 to 7	Config-RW
CNTBaseN	CNTVOFF	Config-RO
CNTEL0BaseN	CNTVOFF	Config-RO

In an implementation that supports 64-bit atomic accesses, then the CNTVOFF{<n>} register must be accessible as an atomic 64-bit value.

For each implemented CNTBaseN frame, it is IMPLEMENTATION DEFINED whether the timer distinguishes between real time and virtual time.

If the frame<n> timer supports this distinction and bit[1:0] of CNTTIDR.Frame<n> are 1, CNTVOFF<n> is implemented as a RW register in the CNTCTLBase frame. When bit[1] of CNTTIDR.Frame<n> is 0, the encoding in the CNTCTLBase frame is RES0.

In a system that implements both Secure and Non-secure states:

- CNTVOFF<n> is always accessible by Secure accesses.
- CNTNSAR.NS<n> determines whether CNTVOFF<n> is accessible by Non-secure accesses.

If CNTVOFF<n> is not implemented, the register location is RAZ/WI.

CNTVOFF is implemented as a RO register in the CNTBaseN frame when the value of CNTACR<n>.RVOFF is 1, otherwise the encoding in the CNTBaseN frame is RES0.

If CNTVOFF is implemented as a RO register in the CNTBaseN frame, and bit[2] of CNTTIDR.Frame<n> is 1, CNTVOFF is also implemented as a RO register in the CNTEL0BaseN frame. When CNTVOFF is not implemented in the CNTBaseN frame, or when bit[2] of CNTTIDR.Frame<n> is 0, the encoding in CNTEL0BaseN is RES0.

Configurations

CNTVOFF<n> is optional to implement in the external register interface.

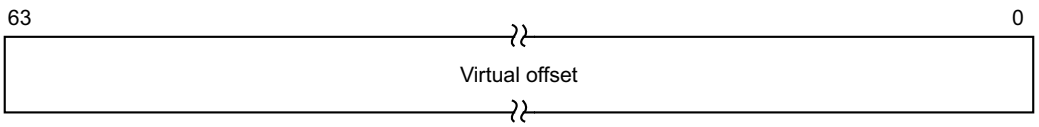
CNTACR<n>.RVOFF enables access to this register for frame CNTBase<n>.

Attributes

CNTVOFF{<n>} is a 64-bit register.

Field descriptions

The CNTVOFF{<n>} bit assignments are:



Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Bits [63:0]

Virtual offset.

Accessing the CNTVOFF{<n>}:

CNTVOFF{<n>} can be accessed through the memory-mapped interface:

Component	Mnemonic	Frame	Offset
Timer	CNTVOFF<n>[31:0]	CNTCTLBase	0x080 + 8n
Timer	CNTVOFF<n>[63:32]	CNTCTLBase	0x084 +8n
Timer	CNTVOFF[31:0]	CNTBaseN	0x018
Timer	CNTVOFF[63:32]	CNTBaseN	0x01C

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

I3.5.20 CounterID<n>, Counter ID registers, n = 0 - 11

The CounterID<n> characteristics are:

Purpose

IMPLEMENTATION DEFINED identification registers 0 to 11 for the memory-mapped Generic Timer.

Usage constraints

This register is accessible as follows:

Default
RO

These registers are accessible by both Secure and Non-secure accesses.

Configurations

These registers are implemented independently in each of the frames accessed through the different memory maps.

If the implementation of the Counter ID registers requires an architecture version, the value for this version of the ARM Generic Timer is version 0.

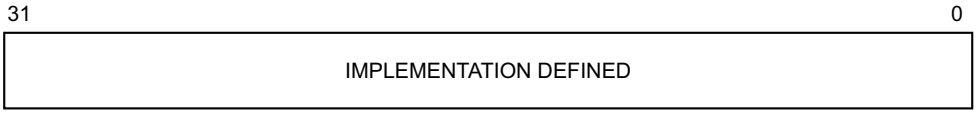
The Counter ID registers can be implemented as a set of CoreSight ID registers, comprising Peripheral ID Registers and Component ID Registers. An implementation of these registers for the Generic Timer must use a Component class value of `0xF`.

Attributes

CounterID<n> is a 32-bit register.

Field descriptions

The CounterID<n> bit assignments are:



IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the CounterID<n>:

CounterID<n> can be accessed through the memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	`0xFD0` + 4n
Timer	CNTReadBase	`0xFD0` + 4n
Timer	CNTBaseN	`0xFD0` + 4n
Timer	CNTEL0BaseN	`0xFD0` + 4n
Timer	CNTCTLBase	`0xFD0` + 4n

Part J

Architectural Pseudocode

Chapter J1
ARMv8 Pseudocode

This chapter contains pseudocode that describes many features of the ARMv8 architecture. It contains the following sections:

- *Pseudocode for AArch64 operations* on page J1-5078.
- *Pseudocode for AArch32 operation* on page J1-5137.
- *Shared pseudocode* on page J1-5209.

Note

Status of this appendix in the beta release document

ARM is currently working to improve the organization and presentation of the pseudocode in this document, including providing improved linking within the pseudocode. Currently, this chapter contains the complete pseudocode library for ARMv8, split between:

- Functions, or versions of functions, that are specific to execution in AArch64 state.
- Functions, or versions of functions, that are specific to execution in AArch32 state.
- Functions that apply to execution in either Execution state.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

J1.1 Pseudocode for AArch64 operations

This section holds the pseudocode for execution in AArch64 state. Functions that are listed in this section are identified as `AArch64.FunctionName`. Some of these functions have an equivalent AArch32 function, `AArch32.FunctionName`. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example `aarch64/debug/breakpoint`.

The top-level sections of the AArch64 pseudocode hierarchy are:

- *aarch64/debug*.
- *aarch64/exceptions* on page J1-5084.
- *aarch64/functions* on page J1-5101.
- *aarch64/instrs* on page J1-5114.
- *aarch64/translation* on page J1-5122.

J1.1.1 aarch64/debug

This section includes the following pseudocode functions:

- *aarch64/debug/breakpoint/AArch64.BreakpointMatch*.
- *aarch64/debug/breakpoint/AArch64.BreakpointValueMatch* on page J1-5079.
- *aarch64/debug/breakpoint/AArch64.StateMatch* on page J1-5080.
- *aarch64/debug/enables/AArch64.GenerateDebugExceptions* on page J1-5081.
- *aarch64/debug/enables/AArch64.GenerateDebugExceptionsFrom* on page J1-5081.
- *aarch64/debug/pmu/AArch64.CheckForPMUOverflow* on page J1-5081.
- *aarch64/debug/pmu/AArch64.CountEvents* on page J1-5082.
- *aarch64/debug/pmu/AArch64.ProfilingProhibited* on page J1-5082.
- *aarch64/debug/takeexceptiondbg/AArch64.TakeExceptionInDebugState* on page J1-5083.
- *aarch64/debug/watchpoint/AArch64.WatchpointByteMatch* on page J1-5083.
- *aarch64/debug/watchpoint/AArch64.WatchpointMatch* on page J1-5084.

aarch64/debug/breakpoint/AArch64.BreakpointMatch

```
// AArch64.BreakpointMatch()
// =========================
// Breakpoint matching in an AArch64 translation regime.

boolean AArch64.BreakpointMatch(integer n, bits(64) vaddress, integer size)
    assert !ELUsingAArch32(S1TranslationRegime());
    assert n <= UInt(ID_AA64DFR0_EL1.BRPs);

    enabled = DBGBCR_EL1[n].E == '1';
    ispriv = PSTATE.EL != EL0;
    linked = DBGBCR_EL1[n].BT == '0x01';
    isbreakpnt = TRUE;
    linked_to = FALSE;

    state_match = AArch64.StateMatch(DBGBCR_EL1[n].SSC, DBGBCR_EL1[n].HMC, DBGBCR_EL1[n].PMC,
                                     linked, DBGBCR_EL1[n].LBN, isbreakpnt, ispriv);
    value_match = AArch64.BreakpointValueMatch(n, vaddress, linked_to);

    if HaveAnyAArch32() && size == 4 then                 // Check second halfword

J1.2 Pseudocode for AArch32 operation

This section holds the pseudocode for execution in AArch32 state. Functions that are listed in this section are identified as `AArch32.FunctionName`. Some of these functions have an equivalent AArch64 function, `AArch64.FunctionName`. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example `aarch32/debug/breakpoint`.

Note

Many AArch32 pseudocode functions have not been updated to show the constraints on the ARMv7 UNPREDICTABLE behaviors that are described in Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*. Where AArch32 pseudocode shows something to be UNPREDICTABLE, check Appendix K1 for possible constraints on the permitted behavior.

The top-level sections of the AArch32 pseudocode hierarchy are:

- *aarch32/debug*.
- *aarch32/exceptions* on page J1-5145.
- *aarch32/functions* on page J1-5163.
- *aarch32/translation* on page J1-5189.

J1.2.1 aarch32/debug

This section includes the following pseudocode functions:

- *aarch32/debug/VCRMatch/AArch32.VCRMatch*.
- *aarch32/debug/authentication/AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled* on page J1-5138.
- *aarch32/debug/breakpoint/AArch32.BreakpointMatch* on page J1-5138.
- *aarch32/debug/breakpoint/AArch32.BreakpointValueMatch* on page J1-5139.
- *aarch32/debug/breakpoint/AArch32.StateMatch* on page J1-5140.
- *aarch32/debug/enables/AArch32.GenerateDebugExceptions* on page J1-5141.
- *aarch32/debug/enables/AArch32.GenerateDebugExceptionsFrom* on page J1-5141.
- *aarch32/debug/pmu/AArch32.CheckForPMUOverflow* on page J1-5141.
- *aarch32/debug/pmu/AArch32.CountEvents* on page J1-5142.
- *aarch32/debug/pmu/AArch32.ProfilingProhibited* on page J1-5142.
- *aarch32/debug/takeexceptiondbg/AArch32.EnterHypModeInDebugState* on page J1-5143.
- *aarch32/debug/takeexceptiondbg/AArch32.EnterModeInDebugState* on page J1-5143.
- *aarch32/debug/takeexceptiondbg/AArch32.EnterMonitorModeInDebugState* on page J1-5144.
- *aarch32/debug/watchpoint/AArch32.WatchpointByteMatch* on page J1-5144.
- *aarch32/debug/watchpoint/AArch32.WatchpointMatch* on page J1-5145.

J1.3 Shared pseudocode

This section holds the pseudocode that is common to execution in AArch64 state and in AArch32 state. Functions listed in this section are identified only by a `FunctionName`, without an `AArch64.` or `AArch32.` prefix. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example `shared/debug/DebugTarget`.

The top-level sections of the shared pseudocode hierarchy are:

- *shared/debug*.
- *shared/exceptions* on page J1-5225.
- *shared/functions* on page J1-5227.
- *shared/translation* on page J1-5279.

J1.3.1 shared/debug

This section includes the following pseudocode functions:

- *shared/debug/ClearStickyErrors/ClearStickyErrors* on page J1-5210.
- *shared/debug/DebugTarget/DebugTarget* on page J1-5210.
- *shared/debug/DebugTarget/DebugTargetFrom* on page J1-5210.
- *shared/debug/DoubleLockStatus/DoubleLockStatus* on page J1-5211.
- *shared/debug/FindWatchpoint/FindWatchpoint* on page J1-5211.
- *shared/debug/authentication/AllowExternalDebugAccess* on page J1-5211.
- *shared/debug/authentication/AllowExternalPMUAccess* on page J1-5211.
- *shared/debug/authentication/Debug_authentication* on page J1-5212.
- *shared/debug/authentication/ExternalInvasiveDebugEnabled* on page J1-5212.
- *shared/debug/authentication/ExternalNoninvasiveDebugEnabled* on page J1-5212.
- *shared/debug/authentication/ExternalSecureInvasiveDebugEnabled* on page J1-5212.
- *shared/debug/authentication/ExternalSecureNoninvasiveDebugEnabled* on page J1-5213.
- *shared/debug/cti/CTI_SetEventLevel* on page J1-5213.
- *shared/debug/cti/CTI_SignalEvent* on page J1-5213.
- *shared/debug/cti/CrossTrigger* on page J1-5213.
- *shared/debug/dccanditr/CheckForDCCInterrupts* on page J1-5213.
- *shared/debug/dccanditr/DBGDTRRX_EL0* on page J1-5213.
- *shared/debug/dccanditr/DBGDTRTX_EL0* on page J1-5214.

Architectural Constraints on UNPREDICTABLE behaviors

This chapter describes the architectural constraints on UNPREDICTABLE behaviors in the ARMv8 architecture. It contains the following sections:

- *AArch32 CONSTRAINED UNPREDICTABLE behaviors* on page K1-5288.
- *AArch64 CONSTRAINED UNPREDICTABLE behaviors* on page K1-5368.

K1.1 AArch32 CONSTRAINED UNPREDICTABLE behaviors

ARMv8 defines architecturally-required constraints on many behaviors that are UNPREDICTABLE in ARMv7. The following sections define those constraints:

- *Overview of the constraints on ARMv7 UNPREDICTABLE behaviors* on page K1-5289.
- *Using R13* on page K1-5289.
- *Using R15* on page K1-5289.
- *Branching into an IT block* on page K1-5290.
- *Branching to an unaligned PC* on page K1-5290.
- *Loads and Stores to unaligned locations* on page K1-5290.
- *CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT* on page K1-5291.
- *Unallocated CP14 and CP15 instructions* on page K1-5292.
- *SBZ or SBO fields in instructions* on page K1-5292.
- *UNPREDICTABLE cases in immediate constants in T32 data-processing instructions* on page K1-5293.
- *UNPREDICTABLE cases in immediate constants in Advanced SIMD instructions* on page K1-5293.
- *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values* on page K1-5293.
- *CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization* on page K1-5294
- *Translation Table Base Address alignment* on page K1-5294.
- *Handling of conceptual coprocessors CP10 and CP11* on page K1-5294.
- *The Performance Monitors Extension* on page K1-5295.
- *Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED* on page K1-5296.
- *Out of range virtual address* on page K1-5296.
- *Instruction fetches from Device memory* on page K1-5297.
- *Multi-access instructions that load the PC from Device memory* on page K1-5297.
- *Programming CSSELR.Level for a cache level that is not implemented* on page K1-5297.
- *Crossing a page boundary with different memory types or Shareability attributes* on page K1-5297.
- *Crossing a 4KB boundary with a Device access* on page K1-5298.
- *CONSTRAINED UNPREDICTABLE behavior for A32 memory hints, Advanced SIMD instructions, and miscellaneous instructions* on page K1-5298.
- *Out of range values of the Set/Way/Index fields in cache maintenance instructions* on page K1-5298.
- *CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instructions in the base instruction set* on page K1-5299.
- *CONSTRAINED UNPREDICTABLE behavior for A32 and T32 system instructions in the base instruction set* on page K1-5344.
- *CONSTRAINED UNPREDICTABLE behavior, A32 and T32 Advanced SIMD and floating-point instructions* on page K1-5351.

- *CONSTRAINED UNPREDICTABLE behaviors associated with the VTCR* on page K1-5362.
- *CONSTRAINED UNPREDICTABLE behavior of EL2 features* on page K1-5363.
- *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5366.
- *CONSTRAINED UNPREDICTABLE behavior in Debug state* on page K1-5367.

K1.1.1 Overview of the constraints on ARMv7 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch32 state, where previous versions of the architecture define behavior as UNPREDICTABLE, the ARMv8-A architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

Note

Software designed to be compatible with the ARMv8-A architecture must not rely on these CONSTRAINED UNPREDICTABLE cases.

K1.1.2 Using R13

In prior versions of the architecture, the use of R13 as a named register specifier was described as UNPREDICTABLE in the pseudocode. In the ARMv8-A architecture, the use of R13 as a named register specifier is not UNPREDICTABLE, unless this is specifically stated, and R13 can be used in the regular form. Bits[1:0] of R13 are not treated as RES0, but can hold any values programmed into them.

K1.1.3 Using R15

All uses of R15 as a named register specifier for a source register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this reference manual must do one of the following:

- Cause the instruction to be treated as an UNDEFINED instruction.
- Cause the instruction to execute as a `NOP`.
- Read the PC with the standard offset that applies for the current instruction set.
- Read the PC with the standard offset that applies for the current instruction set with alignment to a word boundary.
- Read 0.
- Read an UNKNOWN value.

All uses of R15 as a named register specifier for a destination register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this reference manual must do one of the following:

- Cause the instruction to be treated as UNDEFINED.
- Cause the instruction to execute as a `NOP`.
- Ignore the write.
- Branch to an UNKNOWN location in either A32 or T32 state.

The choice between these behaviors might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Instructions that are CONSTRAINED UNPREDICTABLE when the base register is R15 and the instruction specifies a writeback of the base register, are treated as having R15 as both a source register and a destination register.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

For instructions that have two destination registers, for example LDRD, MRRC, and many of the multiply instructions, if Rt, Rt2, RdLo, or RdHi is R15, then the other destination register of the pair is UNKNOWN, if the CONSTRAINED UNPREDICTABLE behavior for the write to R15 is either to ignore the write or to branch to an UNKNOWN location.

For instructions that affect any or all of PSTATE.{N, Z, C, V}, PSTATE.Q, and PSTATE.GE when the register specifier is not R15, any flags affected by an instruction that is CONSTRAINED UNPREDICTABLE when the register specifier is R15 become UNKNOWN,

In addition, for MRC instructions for CP14 and CP15 that use R15 as the destination register descriptor, and thereby target APSR_nzcv where these are described as being CONSTRAINED UNPREDICTABLE, PSTATE.{N, Z, C, V} becomes UNKNOWN.

K1.1.4 Branching into an IT block

Branching into an IT block leads to CONSTRAINED UNPREDICTABLE behavior. Execution starts from the address determined by the branch, but each instruction in the IT block is:

- Executed as if it were not in an IT block. This means that it is executed unconditionally.
- Executed as if it had passed its Condition code check within an IT block.
- Executed as a NOP. That is, it behaves as if it had failed the Condition code check.

K1.1.5 Branching to an unaligned PC

In A32 state, when branching to an address that is not word aligned and is defined to be CONSTRAINED UNPREDICTABLE, one of the following behaviors must occur:

- The unaligned location is forced to be aligned.
- The unaligned address generates an exception on the first instruction using the unaligned PC value.

  If that instruction is executed at EL0 and either of the following applies, the exception is taken to EL2:
  - EL2 is using AArch32 and the value of HCR.TGE is 1
  - EL2 is using AArch64 and the value of HCR_EL2.TGE is 1.

  If the instruction is executed at EL0 when the applicable TGE bit is 0 the exception is taken to EL1.

  If the instruction is executed at an Exception level that is higher than EL0 the exception is taken to the Exception level at which the instruction was executed.

  In all cases, the exception is generated only if the first instruction using the unaligned PC value is architecturally executed.

If the exception that results from a branch to an unaligned PC value:

- Is taken to an Exception level that is using AArch64, it is reported as a Misaligned PC exception, see *Exception from an Illegal Execution state, Misaligned PC, or Misaligned stack pointer* on page D1-1460.
- Is taken to an Exception level that is using AArch32, it is reported as a Prefetch Abort exception, see *Prefetch Abort exception reporting a Misaligned PC exception* on page G1-3715.

Note

Because bit[0] is used for interworking, it is impossible to specify a branch to A32 state when the bottom bit of the target address is 1. Therefore the bottom bit of IFAR, HIFAR, or FAR_ELx is 0 for all these cases.

K1.1.6 Loads and Stores to unaligned locations

Some unaligned loads and stores in the ARMv7 architecture are described as UNPREDICTABLE. These are defined in the ARMv8-A architecture to do one of the following:

- Take an alignment fault.
- Perform the specified load or store to the unaligned memory location.

Non-Confidential - Beta

K1.1.7 CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT

A number of instructions in the architecture are described as being CONSTRAINED UNPREDICTABLE either:

- Anywhere within an IT block.
- As an instruction within an IT block, other than the last instruction within an IT block.

Unless otherwise stated in this manual, when these instructions are committed for execution, one of the following occurs:

- An UNDEFINED exception results.
- The instructions are executed as if they had passed the Condition code check.
- The instructions execute as NOPs. This means that they behave as if they had failed the Condition code check.

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Many instructions that are CONSTRAINED UNPREDICTABLE in an IT block are branch instructions or other non-sequential instructions that change the PC. Where these instructions are not treated as UNDEFINED within an IT block, the remaining iterations of the PSTATE.IT state machine must be treated in one of the following ways:

- PSTATE.IT is cleared to 0.
- PSTATE.IT advances for either a sequential or a nonsequential change of the PC in the same way as it does for instructions that are not CONSTRAINED UNPREDICTABLE that cause a sequential change of the PC.

Note

This does not apply to an instruction that is the last instruction in an IT block.

The instructions addressed by the updated PC must do one of the following:

- Execute as if they had passed the Condition code check for the remaining iterations of the PSTATE.IT state machine.
- Execute as NOPs. That is, they behave as if they had failed the Condition code check for the remaining iterations of the PSTATE.IT state machine.
- Execute as if they were unconditional, or, if the instructions are part of another IT block, in accordance with the behavior described in *Branching into an IT block* on page K1-5290.

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

For exception returns or Debug state exits that cause PSTATE.IT to be set to a reserved value in T32 state or that return to A32 state with a nonzero value in PSTATE.IT, the PSTATE.IT bits are forced to '00000000'. The reserved values are:

```
PSTATE.IT[7:4] != '0000' && PSTATE.IT[3:0] = '0000'
PSTATE.IT[2:0] != '000' when SCTLR/SCTLR_EL_1.ITD == '1'
```

Exception returns or Debug state exits that set PSTATE.IT to a non-reserved value in T32 state can occur when the flow of execution returns to a point:

- Outside an IT block, but with the PSTATE.IT bits set to a value other than '00000000'.
- Inside an IT block, but with a different value of the PSTATE.IT bits than if the IT block had been executed without an exception return or Debug state exit.

In this case the instructions at the target of the exception return or Debug state exit must do one of the following:

- Execute as if they passed the Condition code check for the remaining iterations of the PSTATE.IT state machine.
- Execute as NOPs. That is, they behave as if they failed the Condition code check for the remaining iterations of the PSTATE.IT state machine.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- Execute as if they were unconditional, or as if the instruction were part of another IT block, in accordance with the behavior in *Branching into an IT block* on page K1-5290.

The remaining iterations of the PSTATE.IT state machine must behave in one of the following ways:

- The PSTATE.IT state machine advances as if it were in an IT block.
- The PSTATE.IT bits are ignored.
- The PSTATE.IT bits are forced to `'00000000'`.

K1.1.8 Unallocated CP14 and CP15 instructions

In ARMv8-A, accesses to unallocated CP14 and CP15 register encodings are UNDEFINED.

This includes:

- Reads using encodings that are defined as WO.
- Writes using encodings that are defined as RO.
- `MCR` or `MRC` accesses to using a set of {`CRn`, `opc1`, `CRm`, `opc2`} values that the ARMv7 architecture defined as UNPREDICTABLE.
- CP14 or CP15 accesses that the ARMv7 architecture defined as UNPREDICTABLE when particular functionality was not implemented, when an implementation does not include the Exception level that provides that functionality in ARMv8.

K1.1.9 SBZ or SBO fields in instructions

|Many of the A32 and T32 instructions have (0) or (1) in the instruction decode to indicate *should-be-zero*, SBZ, or *should-be-one*, SBO. Except for the specific cases called out in *CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instructions in the base instruction set* on page K1-5299, if the instruction bit pattern of an instruction is executed with these fields not having the *should be* values, one of the following must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction operates as if the bit had the *should-be* value.
- Any destination registers of the instruction become UNKNOWN.

The exceptions to this rule are:

- *LDM/LDMIA/LDMFD (T32)* on page K1-5303.
- *LDMDB/LDMEA* on page K1-5305.
- *LDR (literal)* on page K1-5306.
- *LDRB (literal)* on page K1-5308.
- *LDRH (literal)* on page K1-5313.
- *LDRSB (literal)* on page K1-5314.
- *LDRSH (literal)* on page K1-5316.
- *LDRD (immediate)* on page K1-5309.
- *LDRD (register)* on page K1-5310.
- *LDRD (literal)* on page K1-5310.
- *POP (T32)* on page K1-5318.
- *POP (A32)* on page K1-5318.
- *PUSH* on page K1-5319.
- *SDIV* on page K1-5322.
- *UDIV* on page K1-5343.
- *STM (STMIA, STMEA)* on page K1-5326.
- *STMDB (STMFD)* on page K1-5327.

K1.1.10 UNPREDICTABLE cases in immediate constants in T32 data-processing instructions

The description of immediate constants in T32 data processing *Modified immediate constants in T32 instructions* on page F2-2336 include constant values that were UNPREDICTABLE in ARMv7. *Instruction encodings* on page F2-2318 describes 32-bit T32 instructions as {hw1, hw2}, where hw1 is the left-hand halfword in the 32-bit encoding diagram for the instruction. The UNPREDICTABLE cases are those where both:

- hw2[7:0] == 0b0000000.
- hw1[10] == 0 and either:
  - hw2[14:12] == 0b001.
  - hw2[14:12] == 0b010.
  - hw2[14:12] == 0b011.

In ARMv8 the CONSTRAINED UNPREDICTABLE behavior is that these encodings produce the value 0b0000000.

K1.1.11 UNPREDICTABLE cases in immediate constants in Advanced SIMD instructions

The description of immediate constants in *Modified immediate constants in T32 and A32 Advanced SIMD instructions* on page F2-2338 include constant values that were UNPREDICTABLE in ARMv7. The UNPREDICTABLE cases are those where:

- The bits that the encoding diagram shows as abcd are all 0.

  In the A32 encoding these are bits[24, 18:6, 3:0]. In the T32 encoding they are bits {hw1[12, 2:0], hw2[3:0]}.

- The bits that the encoding diagram shows as cmode[3:1] are one of {0b001, 0b010, 0b011, 0b101, 0b110}.

  In the A32 encoding these are bits[11:9]. In the T32 encoding they are bits hw2[11:9].

In ARMv8 the CONSTRAINED UNPREDICTABLE behavior is that these encodings produce an immediate constant value of zero.

K1.1.12 CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values

The ARM architecture allows copies of control values or data values to be cached in a cache or TLB. This can lead to CONSTRAINED UNPREDICTABLE behavior if the cache or TLB has not been correctly invalidated following a change of the control or data values.

Unless explicitly stated otherwise, the behavior of the PE is consistent with:

- The old data or control value.
- The new data or control value.
- An amalgamation of the old and new data or control values.

Note

This rules applies where inadequate invalidation of the TLB might cause multiple hits within the TLB. In this situation, a failure to invalidate the TLB by code running at a given Privilege level must not make access to regions of memory with permissions or attributes that could not be accessed at that Privilege level possible.

Alternatively, an implementation might generate a Data Abort exception when detecting multiple hits within a TLB, using the TLB Conflict fault code.

The choice between these behaviors might, in some implementations, vary for each use of a control or data value.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

K1.1.13 CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization

The ARM architecture requires that changes to System registers must be synchronized before they take effect. This can lead to CONSTRAINED UNPREDICTABLE behavior if the synchronization has not been performed.

In these cases, the behavior of the processor is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.

In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.

K1.1.14 Translation Table Base Address alignment

A misaligned Translation Table Base Address can occur if:

- The VMSAv8-32 Short-descriptor translation table format is enabled and TTBR0[13-N:7], which is defined to be RES0, contains one or more nonzero values.
- The VMSAv8-32 Long-descriptor translation table format is enabled, and TTBR0[x-1:3], TTBR1[x-1:3], HTTBR[x-1:3], or VTTBR[x-1:3], which are defined to be RES0, contain one or more nonzero values.

In the event of a misaligned Translation Table Base Address, one of the following behaviors must occur:

- The field that is defined to be RES0 is treated as if all bits were zero:
  - The value that is read back might be the value written or it might be zero.
- The calculation of an address for a translation table walk using that register might be corrupted in those bits that are nonzero.

K1.1.15 Handling of conceptual coprocessors CP10 and CP11

The floating-point instruction set covers both of the conceptual coprocessors CP10 and CP11. This means that CPACR, HCPTR, and NSACR all have control bits whose naming reflects the {CP10, CP11} coprocessors. If these control bits differ, then the behavior is the same as if the control bit for CP11 were equal to the control bit for CP10 in all respects, other than the value read back by a direct read of the CP11 control bit. After a register write that writes different values to the CP10 and CP11 control bits, a direct read of the register might return an UNKNOWN value for the CP11 control bit.

Note

This means that, when different values are written to the CP10 and CP11 control bits in a single register, the architecture permits but does not require that a read of that register returns the value written to the CP11 control bit.

CONSTRAINED UNPREDICTABLE CPACR and NSACR settings

If CPACR.cp<n> contains the encoding `'10'`, then one of the following behaviors must occur:

- The encoding maps onto any of the allocated values, but otherwise does not cause UNPREDICTABLE behavior.
- The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.

Note

In ARMv7, CPACR had a D32DIS bit, and NSACR had an NSD32DIS bit. There is no CPACR.D32DIS or NSACR.NSD32DIS in ARMv8-A, and the corresponding bits in the two registers are RES0.

K1.1.16 The Performance Monitors Extension

The following subsections describe CONSTRAINED UNPREDICTABLE behaviors in AArch32 use of the Performance Monitors Extension:

- *CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPER or PMXEVCNTR*.
- *CONSTRAINED UNPREDICTABLE accesses to PMEVCNTR<n> and PMEVTYPER<n>* on page K1-5296.
- *CONSTRAINED UNPREDICTABLE behavior caused by HDCR.HPMN* on page K1-5296.

CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPER or PMXEVCNTR

The following cases can cause CONSTRAINED UNPREDICTABLE behavior:

- If PMSELR.SEL is not equal to 31, and PMSELR.SEL is greater than or equal to PMCR.N, and the PE is executing in Secure state or in Non-secure Hyp mode.
- If PMSELR.SEL is not 31, and PMSELR.SEL is greater than or equal to HDCR.HPMN, and the PE is executing in a Non-secure mode other than Hyp mode.

In these UNPREDICTABLE cases, one of the following behaviors must occur:

- Accesses to PMXEVTYPER or PMXEVCNTR from that mode are UNDEFINED.
- Accesses to PMXEVTYPER or PMXEVCNTR from that mode behave as RAZ/WI.
- Accesses to PMXEVTYPER or PMXEVCNTR from that mode execute as NOPs.
- Accesses to PMXEVTYPER or PMXEVCNTR from that mode behave as if PMSELR.SEL contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.
- Accesses to PMXEVTYPER or PMXEVCNTR behave as if PMSELR.SEL is 31.
- In Non-secure state, for an access to PMXEVTYPER or PMXEVCNTR from PL1 or a permitted access from PL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2. Accesses from PL0 are permitted when:
  - EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
  - EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

If PMSELR.SEL is equal to 31, then one of the following behaviors must occur:

- Accesses to PMXEVCNTR are UNDEFINED.
- Accesses to PMXEVCNTR behave as RAZ/WI.
- Accesses to PMXEVCNTR execute as NOPs.
- Accesses to PMXEVCNTR behave as if PMSELR.SEL contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.
- In Non-secure state, for an access to PMXEVCNTR from PL1 or a permitted access from PL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2. Accesses from PL0 are permitted when:
  - EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
  - EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

Note

In an implementation that includes EL2, in Non-secure state at PL0 and PL1, HDCR.HPMN, or MDCR_EL2.HPMN, identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

CONSTRAINED UNPREDICTABLE accesses to PMEVCNTR<n> and PMEVTYPER<n>

If <n> is greater than the number of counters available in the current Exception level and state, reads and writes of PMEVCNTR<n> and PMEVTYPER<n> are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a `NOP`.
- In Non-secure state, for an access to PMEVCNTR<n> or PMEVTYPER<n> from PL1 or a permitted access from PL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2. Accesses from PL0 are permitted when:
  - EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
  - EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

Note

In an implementation that includes EL2, in Non-secure state at PL0 and PL1, HDCR.HPMN, or MDCR_EL2.HPMN, identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.

CONSTRAINED UNPREDICTABLE behavior caused by HDCR.HPMN

If HDCR.HPMN is set to 0 or to a value greater than PMCR.N, then the CONSTRAINED UNPREDICTABLE behavior is:

- The value returned by a direct read of HDCR.HPMN is UNKNOWN.
- Either:
  - An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if HDCR.HPMN is set to an UNKNOWN non-zero value less than PMCR.N.
  - All counters are reserved for EL2 use, meaning no counters are accessible from Non-secure EL1 and Non-secure EL0.

K1.1.17 Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED

When a CONSTRAINED UNPREDICTABLE instruction is treated as UNDEFINED, this generates an exception:

- If this exception is taken to an Exception level that is using AArch64 then ESR_ELx is UNKNOWN.
- If this exception is taken to EL2 and EL2 is using AArch32, then the HSR is UNKNOWN.

Note

The value written to ESR or HSR must be consistent with a value that could be created as the result of an exception from the same Exception level that generated the exception, but resulted from a situation that is not CONSTRAINED UNPREDICTABLE at that Exception level. This is to avoid a possible privilege violation.

K1.1.18 Out of range virtual address

If the PE executes an instruction for which the instruction address, size, and alignment mean it contains the bytes `0xFFFF FFFF` and `0x0000 0000`, then the bytes that wrap around and appear to be from `0x0000 0000` onwards come from an UNKNOWN address.

If the PE executes a load or store instruction for which the computed address, total access size, and alignment mean it accesses bytes `0xFFFF FFFF` and `0x0000 0000`, then the bytes that wrap around and appear to be from `0x0000 0000` onwards come from an UNKNOWN address.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

K1.1.19 Instruction fetches from Device memory

Instruction fetches from Device memory are CONSTRAINED UNPREDICTABLE.

If a location in memory has the Device attribute and is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location when address translation is enabled.

If a branch causes the program counter to point to a location in memory with the Device attribute that is not marked as execute-never for the current Exception level for instruction fetches, then an implementation must perform one of the following behaviors:

- It treats the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
- It generates a Permission fault.

K1.1.20 Multi-access instructions that load the PC from Device memory

Multi-access instructions that load the PC from Device memory when address translation is enabled are UNPREDICTABLE in AArch32 state. In the ARMv8-A architecture in AArch32, an implementation must perform one of the following behaviors:

- It loads the PC from the memory location as if the memory location had the Normal Non-cacheable attribute.
- It generates a permission fault.

K1.1.21 Programming CSSELR.Level for a cache level that is not implemented

If CSSELR.Level is programmed to a cache level that is not implemented, then a read of CSSELR returns an UNKNOWN value in CSSELR.Level.

If the CSSELR.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR an implementation must perform one of the following behaviors:

- The CCSIDR read executes as a `NOP`.
- The CCSIDR read is UNDEFINED.
- The CCSIDR read returns an UNKNOWN value.

K1.1.22 Crossing a page boundary with different memory types or Shareability attributes

A memory access from a load or store instruction that crosses a page boundary to a memory location that has a different memory type or Shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the first address accessed by the instruction.
- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the last address accessed by the instruction.
- Each memory access generated by the instruction uses the memory type and Shareability attribute associated with its own address.
- The instruction generates an alignment fault caused by the memory type.

  For the Non-secure PL1&0 translation regime:

  — If the stage 1 translation causes the mismatch then the resulting exception is taken to PL1.

  — If the stage 2 translation causes the mismatch then the resulting exception is taken to PL2.

  — If both stages of translation cause the mismatch then the resulting exception can be taken to either PL1 or PL2.
- The instruction executes as a `NOP`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

K1.1.23 Crossing a 4KB boundary with a Device access

A memory access from a load or store instruction to Device memory that crosses a 4KB boundary results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses.
- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses, except that there is no guarantee of ordering between memory accesses.
- The instruction generates an Alignment fault caused by the memory type.

  For the Non-secure PL1&0 translation regime:

  — If the stage 1 translation causes the boundary to be crossed then the resulting exception is taken to PL1.

  — If the stage 2 translation causes the boundary to be crossed then the resulting exception is taken to PL2.

  — If both stages of translation cause the boundary to be crossed then the resulting exception can be taken to either PL1 or PL2.
- The instruction executes as a `NOP`.

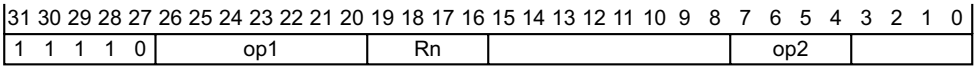
Note

The boundary referred to is between two Device memory regions that are both of 4KB and aligned to 4KB.

K1.1.24 CONSTRAINED UNPREDICTABLE behavior for A32 memory hints, Advanced SIMD instructions, and miscellaneous instructions

In the A32 instruction set, a number of memory hints, Advanced SIMD instructions, and miscellaneous A32 instructions can result in CONSTRAINED UNPREDICTABLE behavior.

The top level encoding of these instructions, as given in the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*, is:



For instructions in this encoding space that ARMv7 shows as UNPREDICTABLE:

- If the instruction does not have an encoding with `Op1= 101x001`, `Op2 = -`, and `Rn = 1111`, then the CONSTRAINED UNPREDICTABLE behavior is that an implementation must treat the encodings in one of the following ways:

  — The encoding is UNDEFINED.

  — The instruction executes as a `NOP`.
- For an instruction with `Op1= 101x001`, `Op2 = -`, and `Rn = 1111`, *PLD (literal)* on page F5-2769 describes the behavior. This encoding is subject to the rules outlined in *SBZ or SBO fields in instructions* on page K1-5292.

Note

This manual restructures the description of the encoding of these A32 instructions. A future release of this manual will update this section to more clearly identify the scope of the section in relation to that restructured description.

K1.1.25 Out of range values of the Set/Way/Index fields in cache maintenance instructions

In the cache maintenance by set/way instructions DCCISW, DCCSW, and DCISW, if any set/way/index argument is larger than the value supported by the implementation, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

Note

This CONSTRAINED UNPREDICTABLE behavior applies, also, to the A64 cache maintenance by set/way instructions DC CISW, DC CSW, and DC ISW.

K1.1.26 CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instructions in the base instruction set

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 instructions listed in *Alphabetical list of T32 and A32 base instruction set instructions* on page F5-2476.

Note

- The pseudocode used in this section to describe cases that can result in CONSTRAINED UNPREDICTABLE behavior does not necessarily match the encoding specific pseudocode for a specific instruction.
- If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

BFC

For a description of these instructions and the encodings, see *BFC* on page F5-2526.

CONSTRAINED UNPREDICTABLE behavior

If `msbit < lsbit`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The output value in the registers is UNKNOWN.

BFI

For a description of these instructions and the encodings, see *BFI* on page F5-2528.

CONSTRAINED UNPREDICTABLE behavior

If `msbit < lsbit`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The output value in the registers is UNKNOWN.

BKPT

For a description of this instruction and the encoding, see *BKPT* on page F5-2537.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `cond != '1110' && cond != '1111'`, then one of the following behaviors occurs:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- The instruction executes unconditionally.
- The instruction executes conditionally.

For the treatment of the case where `cond == '1111'` see *CONSTRAINED UNPREDICTABLE behavior for A32 memory hints, Advanced SIMD instructions, and miscellaneous instructions* on page K1-5298.

CLZ

For a description of this instruction and the encoding, see *CLZ* on page F5-2550.

CONSTRAINED UNPREDICTABLE behavior

For the T1 encoding:

- If `!consistent(Rm)`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The register specified by `hw1`[3:0] is used as the source register.
  - The register specified by `hw2`[3:0] is used a the source register.
  - The value in the destination register is UNKNOWN.

CMP (register)

For a description of this instruction and the encoding, see *CMP (register)* on page F5-2558.

CONSTRAINED UNPREDICTABLE behavior

For the T2 encoding:

- If `n < 8 && m < 8`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the comparison between Rn and Rm.
  - The condition flags become UNKNOWN.

CRC32, CRC32C

For a description of this instruction and the encoding, see *CRC32* on page F5-2565 and *CRC32C* on page F5-2567.

CONSTRAINED UNPREDICTABLE behavior

If `size == 64`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction behaves as if `sz == '10'`.

For the A1 encoding:

- If `cond != '1110'`, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction is executed unconditionally.
- The instruction is executed conditionally.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

HLT

For a description of this instruction and the encoding, see *HLT* on page F5-2587.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `cond != '1110' && cond != '1111'`, then one of the following behaviors occurs:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction is executed unconditionally.
  - The instruction is executed conditionally.

For the treatment of the case where `cond == '1111'` see *CONSTRAINED UNPREDICTABLE behavior for A32 memory hints, Advanced SIMD instructions, and miscellaneous instructions* on page K1-5298.

IT

For a description of this instruction and the encoding, see *IT* on page F5-2592.

CONSTRAINED UNPREDICTABLE behavior

For the T1 encoding:

- If `firstcond == '1111'||(firstcond == '1110' && BitCount(mask)!= 1)` then one of the following behaviors occurs:
  - The instruction is undefined.
  - The instruction executes as a `NOP`.
  - `firstcond == '1111'` is treated the same as `firstcond` == '1110', meaning the always condition, and the PSTATE.IT state machine is progressed in the same way as for any other `cond_base` value.

LDAEX

For a description of this instruction and the encoding, see *LDAEX* on page F5-2596.

CONSTRAINED UNPREDICTABLE behavior

If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

LDAEXB

For a description of this instruction and the encoding, see *LDAEXB* on page F5-2598.

CONSTRAINED UNPREDICTABLE behavior

If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

LDAEXD

For a description of this instruction and the encoding, see *LDAEXD* on page F5-2600.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

For the T1 encoding:

- If `t == t2`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

For the A1 encoding:

- If `Rt<0>=='1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The behavior is the same as if the `Rt<0>=='0'`.
  - The registers accessed are both specified by Rt. This means that Rt and Rt+1 are the same, and both have bit[0] == 1.
  - The registers accessed are specified by Rt and Rt+1.

Note

If `t2 == 15`, then the requirements described in *Using R15* on page K1-5289 apply.

LDAEXH

For a description of this instruction and the encoding, see *LDAEXH* on page F5-2602.

CONSTRAINED UNPREDICTABLE behavior

If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

LDC/LDC2 (literal)

For a description of this instruction and the encoding, see *LDC, LDC2 (literal)* on page F5-2610.

CONSTRAINED UNPREDICTABLE behavior

If `W == '1' || (P == '0' && CurrentInstrSet() != InstrSet_ARM)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The load instruction operates without writeback.

  Note

  This is consistent with ignoring writes to the PC.

- The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, see *Using R15* on page K1-5289.

LDM/LDMIA/LDMFD (A32)

For a description of this instruction and the encoding, see *LDM, LDMIA, LDMFD* on page F5-2613.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as an `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.
- If `wback && registers<n> == '1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the loads using the specified addressing mode, and the content of the register being written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

LDM/LDMIA/LDMFD (T32)

For a description of this instruction and the encoding, see *LDM, LDMIA, LDMFD* on page F5-2613.

CONSTRAINED UNPREDICTABLE behavior

For the T1 encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as an `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

For the T2 encoding:

- If `BitCount(registers) < 2`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction loads a single register using the specified addressing modes.
  - The instruction operates as an `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.
- If `hw2`[13] is set to 1, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the loads using the specified addressing mode, but R13 is UNKNOWN.

    Note

    This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page K1-5292.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- If `P == '1' && M == '1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.
- If `wback && registers<n> == '1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the loads using the specified addressing mode, and the content of the register being written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

LDMDA/LDMFA

For a description of this instruction and the encoding, see *LDMDA, LDMFA* on page F5-2620.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as an `LDM` with the same addressing mode, but targeting an unspecified set of registers. These registers might include R15.
- If `wback && registers<n> == '1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

LDMIB/LDMED

For a description of this instruction and the encoding, see *LDMIB, LDMED* on page F5-2624.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as an `LDM` with the same addressing mode, but targeting an unspecified set of registers. These registers might include R15.
- If `wback && registers<n> == '1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

Non-Confidential - Beta

LDMDB/LDMEA

For a description of this instruction and the encoding, see *LDMDB, LDMEA* on page F5-2622.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `wback && registers<n> == '1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

For the A1 encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED
  - The instruction executes as a `NOP`.
  - The instruction operates as an `LDM` with the same addressing mode, but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

For the T1 encoding:

- If `BitCount(registers) < 2`, one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction loads a single register using the specified addressing modes.
  - The instruction operates as an `LDM` with the same addressing mode, but targeting an unspecified set of registers. These registers might include R15.
- If `hw2`[13] is set to 1, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the loads using the specified addressing mode, but R13 is UNKNOWN.

  Note

  This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page K1-5292.
- If `P == '1' && M == '1'`, then one of the following behaviors must occur:
  - The instruction is undefined.
  - The instruction executes as a `NOP`.
  - The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

LDR (immediate, A32)

For a description of this instruction and the encoding, see *LDR (immediate)* on page F5-2626.

CONSTRAINED UNPREDICTABLE behavior

For the A1encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDR (immediate, T32)

For a description of this instruction and the encoding, see *LDR (immediate)* on page F5-2626.

CONSTRAINED UNPREDICTABLE behavior

For the T4 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDR (literal)

For a description of this instruction and the encoding, see *LDR (literal)* on page F5-2630.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If bit[24] has the same value as bit[21]:
  - The instruction is UNDEFINED.
  - The instruction is treated as a `NOP`.
  - The instruction is treated as if bit[24] had value of 1 and bit[21] had a value of 0.
  - The instruction treats bit[24] as the P bit, and bit[21] as the writeback bit, and uses the same addressing mode as described in the immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

    Note

    This is an exception to the principle in *SBZ or SBO fields in instructions* on page K1-5292.

- If bit[24] == 0 and bit[21] == 1, then the instruction can be handled according to the requirements described in *SBZ or SBO fields in instructions* on page K1-5292 or the requirements described in *LDR (immediate, T32)*.

LDR (register, A32)

For a description of this instruction and the encoding, see *LDR (register)* on page F5-2632.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRB (immediate, A32)

For a description of this instruction and the encoding, see *LDRB (immediate)* on page F5-2635.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRB (immediate, T32)

For a description of this instruction and the encoding, see *LDRB (immediate)* on page F5-2635.

CONSTRAINED UNPREDICTABLE behavior

For the T3 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

Non-Confidential - Beta

LDRB (literal)

For a description of this instruction and the encoding, see *LDRB (literal)* on page F5-2638.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If bit[24] has the same value as bit[21]:
  - The instruction is UNDEFINED.
  - The instruction is treated as a NOP.
  - The instruction is treated as if bit[24] had value of 1 and bit[21] had a value of 0.
  - The instruction treats bit[24] as the P bit, and bit[21] as the writeback bit, and uses the same addressing mode as described in the immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

    Note

    This is an exception to the principle in *SBZ or SBO fields in instructions* on page K1-5292.

- If bit[24] == 0 and bit[21] == 1, then the instruction can be handled according to the requirements described in *SBZ or SBO fields in instructions* on page K1-5292 or the requirements described in *LDRB (immediate, T32)* on page K1-5307.

LDRB (register)

For a description of this instruction and the encoding, see *LDRB (register)* on page F5-2640.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRBT

For a description of this instruction and the encoding, see *LDRBT* on page F5-2642.

CONSTRAINED UNPREDICTABLE behavior

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

- When the Rn field specifies R15, then this instruction can be treated either as described in this section or as described in *LDRB (literal)* on page K1-5308.

LDRD (immediate)

For a description of this instruction and the encoding, see *LDRD (immediate)* on page F5-2644.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `wback && (n == t || n == t2)`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

For the T1 encoding:

- If `t == t2`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

For the A1 encoding:

- If `P=='0' && W=='1'` then one of the following behaviors must occurs:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction behaves as if the values of P and W were as follows:

    `P == '1' && W == '0'`

    `P == '1' && W == '1'`

    `P == '0' && W == '0'`
- If `Rt<0>=='1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The behavior is the same as if `Rt<0> =='0'`.
  - The register accessed are both specified by Rt. This means that Rt and Rt+1 are the same, and both have bit[0] == 1.
  - The registers accessed are specified by Rt and Rt+1.

    Note

    This does not apply if `Rt=='1111'`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

LDRD (literal)

For a description of this instruction and the encoding, see *LDRD (literal)* on page F5-2646.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If bit[24] and bit[21] do not have their *should be* values, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction is treated as if the bits had their *should be* values.
- If `Rt<0>=='1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The behavior is the same as if `Rt<0> =='0'`.
  - The registers accessed are both specified by Rt. This means that Rt and Rt+1 are the same, and both have bit[0] equal to 1.
  - The registers accessed are specified by Rt and Rt+1.

    Note

    This does not apply if `Rt=='1111'`.

For the T1 encoding:

- If `t == t2`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.
- If `W == '1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction is treated as if `W == '0'`.
  - The instruction uses the P and W bits as described for *LDRD (immediate)* on page K1-5309.

LDRD (register)

For a description of this instruction and the encoding, see *LDRD (register)* on page F5-2648.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `wback && (n == t || n == t2)`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- If `P == '0' && W == '1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction behaves as if the values of P and W were as follows:

    `P == '1' && W == '0'`

    `P == '1' && W == '1'`

    `P == '0' && W == '0'`
- If `m == t || m ==t2`, then one of the following behaviors must occur;
  - The instruction is UNDEFINED.
  - The instruction is treated as a `NOP`.
  - The instruction loads register Rm with an UNKNOWN value.
- If `Rt<0>=='1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The behavior is the same as if `Rt<0> == '0'`.
  - The registers accessed are both specified by Rt. This means that Rt and Rt+1 are the same, and in both cases bit[0] == 1.
  - The registers accessed are specified by Rt and Rt+1.

    Note

    This does not apply if `Rt=='1111'`.

LDREX

For a description of this instruction and the encoding, see *LDREX* on page F5-2650.

CONSTRAINED UNPREDICTABLE behavior

If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

LDREXB

For a description of this instruction and the encoding, see *LDREXB* on page F5-2652.

CONSTRAINED UNPREDICTABLE behavior

If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

Non-Confidential - Beta

LDREXD

For a description of this instruction and the encoding, see *LDREXD* on page F5-2654.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

For the T1 encoding:

- If `t == t2`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

For the A1 encoding:

- If `Rt<0>=='1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The behavior is the same as if the `Rt<0>=='0'`.
  - The registers accessed are both specified by Rt. This means that Rt and Rt+1 are the same, and both have bit[0] == 1.
  - The registers accessed are specified by Rt and Rt+1.

Note

If `t2 == 15`, then the requirements described in *Using R15* on page K1-5289 apply.

LDREXH

For a description of this instruction and the encoding, see *LDREXH* on page F5-2656.

CONSTRAINED UNPREDICTABLE behavior

If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

LDRH (immediate, A32)

For a description of this instruction and the encoding, see *LDRH (immediate)* on page F5-2658.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRH (immediate, T32)

For a description of this instruction and the encoding, see *LDRH (immediate)* on page F5-2658.

CONSTRAINED UNPREDICTABLE behavior

For the T3 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRH (literal)

For a description of this instruction and the encoding, see *LDRH (literal)* on page F5-2661.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If bit[24] has the same value as bit[21]:
  - The instruction is UNDEFINED.
  - The instruction is treated as a `NOP`.
  - The instruction is treated as if bit[24] had value of 1 and bit[21] had a value of 0.
  - The instruction treats bit[24] as the P bit, and bit[21] as the writeback bit, and uses the same addressing mode as described in the immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

    Note

    This is an exception to the principle in *SBZ or SBO fields in instructions* on page K1-5292.

- If bit[24] == 0 and bit[21] == 1, then the instruction can be handled according to the requirements described in *SBZ or SBO fields in instructions* on page K1-5292 or the requirements described in *LDRH (immediate, T32)*.

LDRH (register)

For a description of this instruction and the encoding, see *LDRH (register)* on page F5-2663.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRHT

For a description of this instruction and the encoding, see *LDRHT* on page F5-2665.

CONSTRAINED UNPREDICTABLE behavior

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

When the Rn field specifies R15, then this instruction can be treated either as described in this section or as described in *LDRH (literal)* on page K1-5313.

LDRSB (immediate)

For a description of this instruction and the encoding, see *LDRSB (immediate)* on page F5-2667.

CONSTRAINED UNPREDICTABLE behavior

For the A1 and T2 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRSB (literal)

For a description of this instruction and the encoding, see *LDRSB (literal)* on page F5-2670.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If bit[24] has the same value as bit[21]:
  - The instruction is UNDEFINED.
  - The instruction is treated as a `NOP`.
  - The instruction is treated as if bit[24] had value of 1 and bit[21] had a value of 0.
  - The instruction treats bit[24] as the P bit, and bit[21] as the writeback bit, and uses the same addressing mode as described in the immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

    Note

    This is an exception to the principle in *SBZ or SBO fields in instructions* on page K1-5292.

- If bit[24] == 0 and bit[21] == 1, then the instruction can be handled according to the requirements described in *SBZ or SBO fields in instructions* on page K1-5292 or the requirements described in *LDRSB (immediate)* on page K1-5314.

LDRSB (register)

For a description of this instruction and the encoding, see *LDRSB (register)* on page F5-2672.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `wback && (n == t)`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRSBT

For a description of this instruction and the encoding, see *LDRSBT* on page F5-2674.

CONSTRAINED UNPREDICTABLE behavior

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

When the Rn field specifies R15, then this instruction can be treated either as described in this section or as described in *LDRSB (literal)* on page K1-5314.

LDRSH (immediate)

For a description of this instruction and the encoding, see *LDRSH (immediate)* on page F5-2676.

CONSTRAINED UNPREDICTABLE behavior

For the T2 and A1 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

LDRSH (literal)

For a description of this instruction and the encoding, see *LDRSH (literal)* on page F5-2679.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If bit[24] has the same value as bit[21]:
  - The instruction is UNDEFINED.
  - The instruction is treated as a `NOP`.
  - The instruction is treated as if bit[24] had value of 1 and bit[21] had a value of 0.
  - The instruction treats bit[24] as the P bit, and bit[21] as the writeback bit, and uses the same addressing mode as described in the immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

    Note

    This is an exception to the principle in *SBZ or SBO fields in instructions* on page K1-5292.

- If bit[24] == 0 and bit[21] == 1, then the instruction can be handled according to the requirements described in *SBZ or SBO fields in instructions* on page K1-5292 or the requirements described in *LDRSH (immediate)* on page K1-5315.

LDRSH (register)

For a description of this instruction and the encoding, see *LDRSH (register)* on page F5-2681.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRSHT

For a description of this instruction and the encoding, see *LDRSHT* on page F5-2683.

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

When the Rn field specifies R15, then this instruction can be treated either as described in this section or as described in *LDRSB (literal)* on page K1-5314.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

LDRT

For a description of this instruction and the encoding, see *LDRT* on page F5-2685.

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

When the Rn field specifies R15, then this instruction can be treated either as described in this section or as described in *LDRSB (literal)* on page K1-5314.

MOV (register, T32)

For a description of this instruction and the encoding, see *MOV, MOVS (register)* on page F5-2715.

CONSTRAINED UNPREDICTABLE behavior

For the T2 encoding:

- If `InITBlock()`, then one of the following behaviors must occur:
  - The instruction generates an UNDEFINED exception.
  - The instruction is executed as if it passed its condition code check.
  - The instruction executes as a `NOP`. That is, it behaves as if it failed its condition code check.
  - The instruction is treated as MOV Rd, Rm.

Note

This is an exception to the general behavior described in *CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT* on page K1-5291.

MRRC, MRRC2

For a description of this instruction and the encoding, see *MRRC, MRRC2* on page F5-2729.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `t == t2`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The register that is transferred takes an UNKNOWN value.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

MSR (register)

For a description of this instruction and the encoding, see *MSR (register)* on page F5-2741.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `mask == '00'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.

POP (A32)

For a description of this instruction and the encoding, see *POP* on page F5-2778.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If bit[13] is set to 1, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the loads using the specified addressing mode but R13 is UNKNOWN.

For the A2 encoding:

- If `t == 13`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the load using the specified addressing mode but R13 is UNKNOWN.

  Note

  This is an exception to the requirements described in *Using R13* on page K1-5289.

POP (T32)

For a description of this instruction and the encoding, see *POP* on page F5-2778.

CONSTRAINED UNPREDICTABLE behavior

For the T1 encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as a `POP` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

For the T2 encoding:

- If `BitCount(registers) < 2`, one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction loads a single register using the specified addressing modes.
  - The instruction operates as an `LDM` with the same addressing mode but targeting an unspecified set of registers. These might include R15.
- If `hw2` bit[13] is set to 1, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the loads using the specified addressing mode but R13 is UNKNOWN.

    Note

    This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page K1-5292.
- If `P == '1' && M == '1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

For the T3 encoding:

- If `t == 13`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the load using the specified addressing mode but R15 is UNKNOWN.

    Note

    This is an exception to the requirements described in *Using R13* on page K1-5289.

PUSH

For a description of this instruction and the encoding, see *PUSH* on page F5-2784.

CONSTRAINED UNPREDICTABLE behavior

For the T1 encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as a `PUSH` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

For the T2 encoding:

- If `BitCount(registers) < 2`, one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction stores a single register using the specified addressing modes.
  - The instruction operates as a `PUSH` with the same addressing mode but targeting an unspecified set of registers. These might include R15.
- If `hw2` bit[13] is set, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the stores using the specified addressing mode but R13 is UNKNOWN.

    Note

    This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page K1-5292.
- If `hw2` bit[15] is set to 1, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the stores using the specified addressing mode, but R15 is UNKNOWN.

    Note

    This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page K1-5292.

RBIT

For a description of this instruction and the encoding, see *RBIT* on page F5-2807.

CONSTRAINED UNPREDICTABLE behavior

For the T1 encoding:

- If `! Consistent(Rm)`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The register specified by Rm in halfword 1 is used as the source register.
  - The register specified by Rm in halfword 2] is used as the source register.
  - The value in the destination register is UNKNOWN.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

REV

For a description of this instruction and the encoding, see *REV* on page F5-2809.

CONSTRAINED UNPREDICTABLE behavior

For the T2 encoding:

- If `! Consistent(Rm)`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The register specified by Rm in halfword 1 is used as the source register.
  - The register specified by Rm in halfword 2 is used as the source register.
  - The value in the destination register is UNKNOWN.

REV16

For a description of this instruction and the encoding, see *REV16* on page F5-2811.

CONSTRAINED UNPREDICTABLE behavior

For the T2 encoding:

- If `! Consistent(Rm)`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The register specified by Rm in halfword 1 is used as the source register.
  - The register specified by Rm in halfword 2 is used as the source register.
  - The value in the destination register is UNKNOWN.

REVSH

For a description of this instruction and the encoding, see *REVSH* on page F5-2813.

CONSTRAINED UNPREDICTABLE behavior

For the T2 encoding:

- If `! Consistent(Rm)`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The register specified by Rm in halfword 1 is used as the source register.
  - The register specified by Rm in halfword 2 is used as the source register.
  - The value in the destination register is UNKNOWN.

SBFX

For a description of this instruction and the encoding, see *SBFX* on page F5-2856.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `msbit > 31`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The output value in the register is UNKNOWN.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

SDIV

For a description of this instruction and the encoding, see *SDIV* on page F5-2858.

CONSTRAINED UNPREDICTABLE behavior

For the T1encoding:

- If `hw2` bits[15:12] !=‘1111’, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs a divide with no side-effects on other registers.
  - The instruction performs a divide and the register specified by bits[15:12] becomes UNKNOWN.

  Note

  This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page K1-5292.

For the A1 encoding:

- If bits[15:12] !=‘1111’, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs a divide with no side-effects on other registers.
  - The instruction performs a divide and the register specified by bits[15:12] becomes UNKNOWN.

  Note

  This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page K1-5292.

SMLAL

For a description of this instruction and the encoding, see *SMLAL, SMLALS* on page F5-2885.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `dHi == dLo`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The destination register takes an UNKNOWN value.

SMLALBB, SMLALBT, SMLALTB, SMLALTT

For a description of this instruction and the encoding, see *SMLALBB, SMLALBT, SMLALTB, SMLALTT* on page F5-2887.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `dHi == dLo`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The destination register takes an UNKNOWN value.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

SMLALD

For a description of this instruction and the encoding, see *SMLAD, SMLADX* on page F5-2883.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `dHi == dLo`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The destination register takes an UNKNOWN value.

SMLSLD

For a description of this instruction and the encoding, see *SMLSD, SMLSDX* on page F5-2893.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `dHi == dLo`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The destination register takes an UNKNOWN value.

SMULL

For a description of this instruction and the encoding, see *SMULL, SMULLS* on page F5-2907.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `dHi == dLo`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The destination register takes an UNKNOWN value.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

STC, STC2

For a description of this instruction and the encoding, see *STC, STC2* on page F5-2926.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `n == 15 && (wback || CurrentInstrSet() != InstrSet_A32)`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction set uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

Note

Use of R15 by the T32 `STC` instruction is also covered by *Using R15* on page K1-5289.

STLEX

For a description of this instruction and the encoding, see *STLEX* on page F5-2932.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction executes, but the value stored is UNKNOWN.
- If `d == n`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that `t2==15`, then the requirements described in *Using R15* on page K1-5289 apply.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

STLEXB

For a description of this instruction and the encoding, see *STLEXB* on page F5-2934.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction executes, but the value stored is UNKNOWN.
- If `d == n`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that `t2==15`, then the requirements described in *Using R15* on page K1-5289 apply.

STLEXD

For a description of this instruction and the encoding, see *STLEXD* on page F5-2936.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction executes, but the value stored is UNKNOWN.
- If `d == n`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that `t2==15`, then the requirements described in *Using R15* on page K1-5289 apply.

For the A1 encoding:

- If `Rt<0>=='1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The behavior is the same as if `Rt<0>=='0'`.
  - The register accessed are both specified by Rt. For example, Rt and Rt+1 are the same, and both have bit[0] == 1.
  - The registers accessed are specified by Rt and R+1.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

STLEXH

For a description of this instruction and the encoding, see *STLEXH* on page F5-2938.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction executes, but the value stored is UNKNOWN.
- If `d == n`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that `t2==15`, then the requirements described in *Using R15* on page K1-5289 apply.

STM (STMIA, STMEA)

For a description of this instruction and the encoding, see *STM, STMIA, STMEA* on page F5-2941.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.

For the T1 and A1 encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as an `STM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

For the T2 encoding:

- If `BitCount(registers) < 2`, then one of the following behaviors occurs:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction stores a single register using the specified addressing modes.
  - The instruction operates as an `STM` with the same addressing mode but targeting an unspecified set of registers. These might include R15.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- If the value of hw2 bit[13] is 1, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the stores using the specified addressing mode but the value of R13 is UNKNOWN.

  Note

  This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page K1-5292.

- If the value of hw2 bit[15] is 1, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the stores using the specified addressing mode but the value of R15 is UNKNOWN.

  Note

  This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page K1-5292.

- If `wback && registers<n> == '1'`, and that case is defined to be UNPREDICTABLE, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the stores using the specified addressing mode and the value stored for the base register is UNKNOWN.

STMDB (STMFD)

For a description of this instruction and the encoding, see *STMDB, STMFD* on page F5-2947.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.

For the A1 encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

For the T1 encoding:

- If `BitCount(register) < 2`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction stores a single register using the specified addressing mode.
  - The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These might include R15.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- If `wback && registers<n> == '1'`, and that case is defined to be UNPREDICTABLE, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the stores using the specified addressing mode and the value stored for the base register is UNKNOWN.
- If the value of `hw2` bit[13] is 1, then one of the following behaviors occurs:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the stores using the specified addressing mode but the value of R13 is UNKNOWN.

    Note

    This an exception to the requirements described in *SBZ or SBO fields in instructions* on page K1-5292.
- If the value of `hw2` bit[15] is 1, then one of the following behaviors occurs:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the stores using the specified addressing mode but the value of R15 is UNKNOWN.

    Note

    This is an exception to the requirement described in *SBZ or SBO fields in instructions* on page K1-5292.

STMDA (STMED)

For a description of this instruction and the encoding, see *STMDA, STMED* on page F5-2945.

CONSTRAINED UNPREDICTABLE behavior

For the A1encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as an `STM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.
- If the instruction uses R15 as a base register and specifies writeback, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction is performed without writeback.

    Note

    This is consistent with ignoring writes to the PC.
  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.

STMIB (STMFA)

For a description of this instruction and the encoding, see *STMIB, STMFA* on page F5-2949.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as an `STM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.
- If the instruction uses R15 as a base register and specifies writeback, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction is performed without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.
- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.

STR (immediate, A32)

For a description of this instruction and the encoding, see *STR (immediate)* on page F5-2951.

CONSTRAINED UNPREDICTABLE behavior

For the A1encoding:

- If `t == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- If `wback && n == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.

STR (immediate, T32)

For a description of this instruction and the encoding, see *STR (register)* on page F5-2955.

CONSTRAINED UNPREDICTABLE behavior

For the T3 encoding:

- If `t == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.

For the T4 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.

STR (register)

For a description of this instruction and the encoding, see *STR (register)* on page F5-2955.

CONSTRAINED UNPREDICTABLE behavior

For the T2 encoding:

- If `t == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.

For the A1encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

    Note

    Pre-indexed addressing and post-indexed addressing imply writeback.

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.

STRB (immediate, A32)

For a description of this instruction and the encoding, see *STRB (immediate)* on page F5-2958.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `t == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

    Note

    Pre-indexed addressing and post-indexed addressing imply writeback.
- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.

STRB (immediate), T32

For a description of this instruction and the encoding, see *STRB (immediate)* on page F5-2958.

CONSTRAINED UNPREDICTABLE behavior

For the T3 encoding:

- If `t == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- If `wback && n == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

    Note

    Pre-indexed addressing and post-indexed addressing imply writeback.

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.

STRB (register)

For a description of this instruction and the encoding, see *STRB (register)* on page F5-2961.

CONSTRAINED UNPREDICTABLE behavior

For the A1 and T2 encoding:

- If `t == 15` is UNPREDICTABLE, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

    Note

    Pre-indexed addressing and post-indexed addressing imply writeback.

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.

Non-Confidential - Beta

STRBT

For a description of this instruction and the encoding, see *STRBT* on page F5-2963.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `t == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.
  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

STRD (immediate)

For a description of this instruction and the encoding, see *STRD (immediate)* on page F5-2965.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `t == 15` or `t2 == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- If `wback && (n == t || n == t2)`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store of the registers specified using the specified addressing mode but the value of the registers stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.

For the A1 encoding:

- If `Rt<0>=='1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The behavior is the same as if `Rt<0>=='0'`.
  - The registers accessed are both specified by Rt. For example, Rt and Rt+1 are the same, and both have bit[0] equal to 1.
  - The registers accessed are specified by Rt and Rt+1.

    Note

    This does not apply if `Rt=='1111'`.

- If `P == '0' && W == '1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction is treated as a `NOP`.
  - The instruction behaves as if the values of P and W were one of:

    ```
    P == '1' && W == '0'
    P == '1' && W == '1'
    P == '0' && W == '0'
    ```

Non-Confidential - Beta

STRD (register)

For a description of this instruction and the encoding, see *STRD (register)* on page F5-2967.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `t2 == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- If `wback && (n == t || n == t2)`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store of the registers specified using the specified addressing mode but the value of the registers stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

  Note

  Pre-indexed addressing and post-indexed addressing imply writeback.

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.
- If `Rt<0>=='1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The behavior is the same as if `Rt<0>=='0'`.
  - The registers accessed are both specified by Rt. For example, Rt and Rt+1 are the same, and both have bit[0] equal to 1.
  - The registers accessed are specified by Rt and Rt+1.

    Note

    This does not apply if `Rt=='1111'`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- If `P == '0' && W == '1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction is treated as a `NOP`.
  - The instruction behaves as if the values of P and W were one of:
    `P == '1' && W == '0'`
    `P == '1' && W == '1'`
    `P == '0' && W == '0'`

STREX

For a description of this instruction and the encoding, see *STREX* on page F5-2969.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction executes, but the value stored is UNKNOWN.
- If `d == n`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that `t2==15`, then the requirements described in *Using R15* on page K1-5289 apply.

STREXB

For a description of this instruction and the encoding, see *STREXB* on page F5-2971.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction executes, but the value stored is UNKNOWN.
- If `d == n`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that `t2==15`, then the requirements described in *Using R15* on page K1-5289 apply.

Non-Confidential - Beta

STREXD

For a description of this instruction and the encoding, see *STREXD* on page F5-2973.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction executes, but the value stored is UNKNOWN.
- If `d == n`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that `t2==15`, then the requirements described in *Using R15* on page K1-5289 apply.

For the A1 encoding:

- If `Rt<0>=='1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The behavior is the same as if `Rt<0>=='0'`.
  - The register accessed are both specified by Rt. For example, Rt and Rt+1 are the same, and both have bit[0] == 1.
  - The registers accessed are specified by Rt and R+1.

STREXH

For a description of this instruction and the encoding, see *STREXH* on page F5-2975.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction executes, but the value stored is UNKNOWN.
- If `d == n`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that `t2==15`, then the requirements described in *Using R15* on page K1-5289 apply.

Non-Confidential - Beta

STRH (immediate, A32)

For a description of this instruction and the encoding, see *STRH (immediate)* on page F5-2977.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `t == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

    Note

    Pre-indexed addressing and post-indexed addressing imply writeback.

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.

STRH (immediate, T32)

For a description of this instruction and the encoding, see *STRH (immediate)* on page F5-2977.

CONSTRAINED UNPREDICTABLE behavior

For T2 and T3 encodings:

- If `t == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

For the T3 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

STRH (register)

For a description of this instruction and the encoding, see *STRH (register)* on page F5-2980.

CONSTRAINED UNPREDICTABLE behavior

For the T2 and A1 encoding:

- If `t == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- If `wback && n == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

    Note

    Pre-indexed addressing and post-indexed addressing imply writeback.

STRHT

For a description of this instruction and the encoding, see *STRHT* on page F5-2982.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `t == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

    Note

    Pre-indexed addressing and post-indexed addressing imply writeback.

Non-Confidential - Beta

STRT

For a description of this instruction and the encoding, see *STRT* on page F5-2984.

CONSTRAINED UNPREDICTABLE behavior

For the T1 encoding:

- If `t == 15` is UNPREDICTABLE, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page K1-5289 apply.

    Note

    Pre-indexed addressing and post-indexed addressing imply writeback.

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page K1-5289.

UBFX

For a description of this instruction and the encoding, see *UBFX* on page F5-3034.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `msbit > 31`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The output value in the register is UNKNOWN.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

UDIV

For a description of this instruction and the encoding, see *UDIV* on page F5-3038.

CONSTRAINED UNPREDICTABLE behavior

For the T1encoding:

- If `hw2` bits[15:12] !='1111', then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs a divide with no side-effects on other registers.
  - The instruction performs a divide and the register specified by bits[15:12] becomes UNKNOWN.

  Note

  This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page K1-5292.

For the A1 encoding:

- If bits[15:12] !='1111', then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs a divide with no side-effects on other registers.
  - The instruction performs a divide and the register specified by bits[15:12] becomes UNKNOWN.

  Note

  This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page K1-5292.

UMAAL

For a description of this instruction and the encoding, see *UMAAL* on page F5-3052.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `dHi == dLo`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The destination register takes an UNKNOWN value.

UMLAL

For a description of this instruction and the encoding, see *UMLAL, UMLALS* on page F5-3054.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `dHi == dLo`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The destination register takes an UNKNOWN value.

UMULL

For a description of this instruction and the encoding, see *UMULL, UMULLS* on page F5-3056.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `dHi == dLo`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The destination register takes an UNKNOWN value.

K1.1.27 CONSTRAINED UNPREDICTABLE behavior for A32 and T32 system instructions in the base instruction set

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 system instructions.

Note

If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

CPS (A32)

For a description of this instruction and the encoding, see *CPS, CPSID, CPSIE* on page F5-2562.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If the instruction transfers an illegal mode encoding to PSTATE.M, then this invokes an illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

  Note

  - An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.
  - `CPS` executed from User mode acts as a `NOP`.

For the A1 encoding:

- If `(imod == '00 && M =='0') || imod == '01'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
- If `mode != '00000' && M == '0'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as if `M == '1'`.
  - The instruction operates as if `mode == '0000'`.
- If `(imod<1> == '1' && A:I:F == '000')`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction behaves as if `imod<1> == '0'`.
  - The instruction behaves as if `A:I:F` had an UNKNOWN nonzero value.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- If (imod<1> == '0' && A:I:F != 000) then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction behaves as if imod<1> == '1'.
  - The instruction behaves as if A:I:F == 000.

CPS (T32)

For a description of this instruction and the encoding, see *CPS, CPSID, CPSIE* on page F5-2562.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If the instruction transfers an illegal mode encoding to PSTATE.M, then this invokes the illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

  Note

  - An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.
  - CPS executed from User mode acts as a NOP.

For the T1 encoding:

- If A:I:F == '000', then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.

For the T2 encoding:

- If imod == '01', then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
- If mode != '00000' && M == '0', then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as if M =='1'.
  - The instruction behaves as if mode == '0000'.
- If (imod<1> == '1' && A:I:F == '000'), then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction behaves as if imod<1> == '0'.
  - The instruction behaves as if A:I:F had an UNKNOWN nonzero value.
- If (imod<1> == '0' && A:I:F != '000') then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction behaves as if imod<1> == '1'.
  - The instruction behaves as if A:I:F == '000'.

LDM (exception return)

For a description of this instruction and the encoding, see *LDM (exception return)* on page F5-2616.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
- If `wback && registers<n> == '1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register being written back is UNKNOWN. In addition, if an exception occurs during the execution of this instruction, the base address might be corrupted so that the instruction cannot be repeated.
- If the instruction transfers an illegal mode encoding PSTATE.M, then this invokes the illegal exception return.

  Note

  An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

LDM (User registers)

For a description of this instruction and the encoding, see *LDM (User registers)* on page F5-2618.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `BitCount(registers) < 1`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as an `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.
- If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as an `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

MRS

For a description of this instruction and the encoding, see *MRS* on page F5-2731.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode and is accessing the SPSR, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.

MSR (immediate)

For a description of this instruction and the encoding, see *MSR (immediate)* on page F5-2739.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If the instruction is executed in User mode or in System mode and is accessing the SPSR, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
- If `mask == '0000' && R == '1'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.

  If the instruction transfers an illegal mode encoding to PSTATE.M, then this invokes the illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

  Note

  An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

MSR (register)

For a description of this instruction and the encoding, see *MSR (register)* on page F5-2741.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode and is accessing the SPSR, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- If `mask == '0000'`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.

  If the instruction transfers an illegal mode encoding to PSTATE.M, then this invokes the illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

  Note

  An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

RFE

For a description of this instruction and the encoding, see *RFE, RFEDA, RFEDB, RFEIA, RFEIB* on page F5-2815.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
- If the instruction transfers an illegal mode encoding to PSTATE.M, then this invokes the illegal exception return.

  Note

  An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

SRS (T32)

For a description of this instruction and the encoding, see *SRS, SRSDA, SRSDB, SRSIA, SRSIB* on page F5-2913.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
- If the instruction specifies an illegal mode field, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - R13 of the current mode is used.
  - The store occurs to an UNKNOWN address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become UNKNOWN.

Non-Confidential - Beta

SRS (A32)

For a description of this instruction and the encoding, see *SRS, SRSDA, SRSDB, SRSIA, SRSIB* on page F5-2913.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
- If the instruction specifies an illegal mode field, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - R13 of the current mode is used.
  - The store occurs to an UNKNOWN address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become UNKNOWN.

STM (User registers)

For a description of this instruction and the encoding, see *STM (User registers)* on page F5-2943.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `BitCount(registers) < 1`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as an `STM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.
- If the instruction is executed from User mode or System mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as an `STM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

SUBS PC, LR and related instructions (T32)

For a description of this instruction and the encoding, see the exception return form of *SUB, SUBS (immediate)* on page F5-2988.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
- If the instruction transfers an illegal mode encoding to PSTATE.M, then this invokes the illegal exception return.

  Note

  An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

For this encoding:

- If `hw2`[3:0] are `0b1110`, and the instruction is executed when not in Hyp mode, System mode, or User mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction is treated as a `NOP`.
  - The instruction is treated as if `hw2`[3:0] are `0b1110`.
  - The program counter is set using the value in the register specified by `hw2`[3:0].

SUBS PC. LR and related instructions (A32)

For a description of this instruction and the encoding, see the exception return forms of *MOV, MOVS (register)* on page F5-2715 and *SUB, SUBS (immediate)* on page F5-2988.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
- If the instruction transfers an illegal mode encoding to PSTATE.M, then this invokes the illegal exception return.

  Note

  An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

K1.1.28 CONSTRAINED UNPREDICTABLE behavior, A32 and T32 Advanced SIMD and floating-point instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 Advanced SIMD and floating-point instructions listed in *Alphabetical list of floating-point and Advanced SIMD instructions* on page F6-3108.

Note

- The pseudocode used in this section to describe cases that can result in CONSTRAINED UNPREDICTABLE behavior does not necessarily match the encoding specific pseudocode for a specific instruction.
- If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

VCVT (between floating-point and fixed-point)

For a description of this instruction and the encoding, see *VCVT (between floating-point and fixed-point, floating-point)* on page F6-3236.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `frac_bits < 0`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The result of the conversion is UNKNOWN.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD1 (multiple single elements)

For a description of this instruction and the encoding, see *VLD1 (multiple single elements)* on page F6-3296.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d+regs > 32`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

Non-Confidential - Beta

VLD1 (single element to all lanes)

For a description of this instruction and the encoding, see *VLD1 (single element to all lanes)* on page F6-3293.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d+regs > 32`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD2 (multiple 2-element structures)

For a description of this instruction and the encoding, see *VLD2 (multiple 2-element structures)* on page F6-3305.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d2+regs > 32`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD2 (single 2-element structure to one lane)

For a description of this instruction and the encoding, see *VLD2 (single 2-element structure to one lane)* on page F6-3299.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d2 > 31`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

Non-Confidential - Beta

VLD2 (single 2-element structure to all lanes)

For a description of this instruction and the encoding, see *VLD2 (single 2-element structure to all lanes)* on page F6-3302.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d2 > 31`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD3 (multiple 3-element structures)

For a description of this instruction and the encoding, see *VLD3 (multiple 3-element structures)* on page F6-3314.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d3 > 31`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD3 (single 3-element structure to one lane)

For a description of this instruction and the encoding, see *VLD3 (single 3-element structure to one lane)* on page F6-3308.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d3 > 31`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

VLD3 (single 3-element structure to all lanes)

For a description of this instruction and the encoding, see *VLD3 (single 3-element structure to all lanes)* on page F6-3311.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d+regs > 32`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD4 (multiple 4-element structures)

For a description of this instruction and the encoding, see *VLD4 (multiple 4-element structures)* on page F6-3323.

CONSTRAINED UNPREDICTABLE behavior

If `d3 > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD4 (single 4-element structure to one lane)

For a description of this instruction and the encoding, see *VLD4 (single 4-element structure to one lane)* on page F6-3317.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d4 > 31`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

Non-Confidential - Beta

VLD4 (single 4-element structure to all lanes)

For a description of this instruction and the encoding, see *VLD4 (single 4-element structure to all lanes)* on page F6-3320.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d4 > 31`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLDM

For a description of this instruction and the encoding, see *VLDM, VLDMDB, VLDMIA* on page F6-3326.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `regs == 0`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as a `VLDM` or a `VPOP` with the same addressing mode but loads no registers.
- If the register list includes a register that is out of range, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD&FP registers become UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Note

Out of range means that the register list includes:

- A register with a number greater than the number of registers implemented.
- More than 16 double word registers.
- A double word register specified as D16-D31 with an odd value of `imm8`.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VMOV (between two general-purpose registers and two single-precision registers)

For a description of this instruction and the encoding, see *VMOV (between two general-purpose registers and two single-precision registers)* on page F6-3385.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `to_arm_registers && t == t2`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The destination register becomes UNKNOWN.

  If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.
- If `m == 31`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD&FP single-precision registers become UNKNOWN for a move to the single-precision register. The general-purpose registers listed in the instruction become UNKNOWN for a move from the single-precision registers. This behavior does not affect any other general-purpose registers.

VMOV (between two general-purpose registers and a doubleword floating-point register)

For a description of this instruction and the encoding, see *VMOV (between two general-purpose registers and a doubleword floating-point register)* on page F6-3370.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `to_arm_registers && t == t2`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The destination register becomes UNKNOWN.

  If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VMRS

For a description of this instruction and the encoding, see *VMRS* on page F6-3391.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If, in ARMv7, the instruction would have been UNPREDICTABLE because the `reg` field does not specify an accessible Advanced SIMD and floating-point System register, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction transfers an UNKNOWN value to the specified general-purpose register.

  In addition, `CheckVFPEnabled(FALSE)` can be called by this instruction for these CONSTRAINED UNPREDICTABLE cases.

VMSR

For a description of this instruction and the encoding, see *VMSR* on page F6-3393.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If, in ARMv7, the instruction would have been UNPREDICTABLE because the `reg` field does not specify an accessible Advanced SIMD and floating-point System register, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction transfers the value in the general-purpose register to one of the allocated registers accessible using `VMSR` at the same Exception level.

  In addition, `CheckVFPEnabled(FALSE)` can be called by this instruction for these CONSTRAINED UNPREDICTABLE cases.
- For the cases where, in ARMv7, the instruction would have been UNPREDICTABLE because Rt was specified as R15, see *Using R15* on page K1-5289.

VPOP

For a description of this instruction and the encoding, see *VPOP* on page F6-3445.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `regs == 0`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as a `VLDM` or a `VPOP` with the same addressing mode but loads no registers.
- If the register list includes a register that is out of range, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD&FP registers become UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Note

Out of range means that the register list includes:

- A register with a number greater than the number of registers implemented.
- More than 16 double word registers.
- A double word register specified as D16-D31 with an odd value of `imm8`.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VPUSH

For a description of this instruction and the encoding, see *VPUSH* on page F6-3447.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `regs == 0`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as a `VSTM` or `VPUSH` with the same addressing mode but loads no registers.
- If the register list includes a register that is out of range, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

Note

Out of range means that the register list includes:

- A register with a number greater than the number of registers implemented.
- More than 16 double word registers.
- A double word register specified as D16-D31 with an odd value of `imm8`.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST1 (multiple single elements)

For a description of this instruction and the encoding, see *VST1 (multiple single elements)* on page F6-3586.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d+regs > 32`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

— The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST2 (multiple 2-element structures)

For a description of this instruction and the encoding, see *VST2 (multiple 2-element structures)* on page F6-3592.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d2+regs > 32`, then one of the following behaviors must occur:
  - — The instruction is UNDEFINED.
  - — The instruction executes as a `NOP`.
  - — The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST2 (single 2-element structure from one lane)

For a description of this instruction and the encoding, see *VST2 (single 2-element structure from one lane)* on page F6-3589.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d2 > 31`, then one of the following behaviors must occur:
  - — The instruction is UNDEFINED.
  - — The instruction executes as a `NOP`.
  - — The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

Non-Confidential - Beta

VST3 (multiple 3-element structures)

For a description of this instruction and the encoding, see *VST3 (multiple 3-element structures)* on page F6-3598.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d3 > 31`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST3 (single 3-element structure from one lane)

For a description of this instruction and the encoding, see *VST3 (single 3-element structure from one lane)* on page F6-3595.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d3 > 31`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

Non-Confidential - Beta

VST4 (multiple 4-element structures)

For a description of this instruction and the encoding, see *VST4 (multiple 4-element structures)* on page F6-3604.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d4 > 31`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST4 (single 4-element structure from one lane)

For a description of this instruction and the encoding, see *VST4 (single 4-element structure from one lane)* on page F6-3601.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d4 > 31`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VSTM

For a description of this instruction and the encoding, see *VSTM, VSTMDB, VSTMIA* on page F6-3607.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `regs == 0`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as a `VSTM` or `VPUSH` with the same addressing mode but loads no registers.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- If the register list includes a register that is out of range, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

Note

Out of range means that the register list includes:

- A register with a number greater than the number of registers implemented.
- More than 16 double word registers.
- A double word register specified as D16-D31 with an odd value of `imm8`.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VTBL, VTBX

For a description of this instruction and the encoding, see *VTBL, VTBX* on page F6-3625.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `n + length > 32`, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD&FP registers become UNKNOWN. This behavior does not affect any general-purpose registers.

K1.1.29 CONSTRAINED UNPREDICTABLE behaviors associated with the VTCR

The following subsections describe the CONSTRAINED UNPREDICTABLE behavior associated with programming the VTCR:

- *Misprogramming VTCR.S.*
- *CONSTRAINED UNPREDICTABLE combinations of the starting level and size fields* on page K1-5363.

Misprogramming VTCR.S

VTCR.S must be programmed to the value of T0SZ[3], or the effect is CONSTRAINED UNPREDICTABLE. For the ARMv8-A architecture, if VTCR.S is not programmed correctly, then the VTCR.T0SZ value is treated as an UNKNOWN value.

Note

The CONSTRAINED UNPREDICTABLE behavior described in *CONSTRAINED UNPREDICTABLE combinations of the starting level and size fields* on page K1-5363 means the UNKNOWN VTCR.T0SZ value might generate a Translation fault.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

CONSTRAINED UNPREDICTABLE combinations of the starting level and size fields

If the stage 2 input address size, as programmed in VTCR.T0SZ, is out of range with respect to the starting level, as programmed in the VTCR.SL0 field, or the VTCR.SL0 field is programmed to a reserved value, then at the time of a translation walk that uses the stage 2 translation, a stage 2 level 1 Translation Fault is generated.

K1.1.30 CONSTRAINED UNPREDICTABLE behavior of EL2 features

The following sections describe CONSTRAINED UNPREDICTABLE behavior that can occur in an implementation that includes EL2 where EL2 can use AArch32:

- *ERET in User mode or System mode*.
- *Accessing Hyp mode from outside Hyp mode*.
- *Modifying PSTATE.M when in Hyp mode*
- *Use of Hyp mode in Secure state*.
- *Execution of Load/Store unprivileged instructions in Hyp mode* on page K1-5364.
- *Exception return to Hyp mode* on page K1-5364.
- *Accessing registers that cannot be accessed using MSR/MRS instructions* on page K1-5364.
- *Memory type handling* on page K1-5364.
- *Hyp mode TLB maintenance instructions* on page K1-5365.
- *Hyp mode VA to PA address translation instructions* on page K1-5365.
- *Stage 1 default memory type* on page K1-5365.
- *Trapping of general exceptions to Hyp mode* on page K1-5365.
- *Prevention of rootskits using Hyp mode or Secure state* on page K1-5366.
- *HVC* on page K1-5366.
- *MSR/MRS Banked registers* on page K1-5366.

ERET in User mode or System mode

If ERET is executed in User mode or System mode, it behaves as described in *SUBS PC, LR and related instructions (T32)* on page K1-5350.

Accessing Hyp mode from outside Hyp mode

Attempting to change into Hyp mode or out of Hyp mode using the `MSR` or `CPS` instruction invokes the ARMv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

`SRS` using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in *SRS (T32)* on page K1-5348 and *SRS (A32)* on page K1-5349.

Modifying PSTATE.M when in Hyp mode

Attempting to change into Hyp mode or out of Hyp mode using the `MSR` or `CPS` instruction invokes the ARMv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

`SRS` using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in *SRS (T32)* on page K1-5348 and *SRS (A32)* on page K1-5349.

Use of Hyp mode in Secure state

Attempting to change into Hyp mode or out of Hyp mode using the `MSR` or `CPS` instruction invokes the ARMv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

`SRS` using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in *SRS (T32)* on page K1-5348 and *SRS (A32)* on page K1-5349.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Execution of Load/Store unprivileged instructions in Hyp mode

If LDRT, LDRSHT, LDRHT, LDRSBT, LDRBT, STRT, STRHT or STRBT are executed in Hyp mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the equivalent, corresponding LDR, LDRSH, LDRH, LDRSB, LDRB, STR, STRH or STRB instruction in Hyp mode.

Exception return to Hyp mode

Exception returns to Hyp mode when SCR.NS == 0 or from a Non-secure PL1 mode invokes the ARMv8 illegal exception return.

Accessing registers that cannot be accessed using MSR/MRS instructions

The following MSR and MRS instructions can lead to CONSTRAINED UNPREDICTABLE behavior:

```
MSR <Rm>_<mode>, <Rn>

MSR SPSR_<mode>, <Rn>

MSR ELR_hyp, <Rn>

MRS <Rn>, <Rm>_<mode>

MRS <Rn>, SPSR_<mode>

MRS <Rn>, ELR_hyp
```

If these instructions are executed in either Secure or Non-secure User mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If the MSR and MRS instructions attempt to access a register that cannot be legally accessed, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- For MRS instructions, the destination general-purpose register becomes UNKNOWN.
- For MSR instructions, if the register specified could be accessed from the current mode by other mechanisms, then this register is UNKNOWN. Otherwise the instruction executes as a NOP.

Memory type handling

If the attributes for a memory location after combining stage 1 and stage 2 of a translation regime is Normal Inner Non-cacheable, Outer Non-cacheable, then the shareability attributes after combining the two stages of translation is Outer Shareable.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Hyp mode TLB maintenance instructions

If a TLBIMVAH, TLBIMVALH, TLBIMVAHIS, TLBIMVALHIS, TLBIALLH, TLBIALLHIS, TLBIALLNSNH, TLBIALLNSNHIS, TLBIIPAS2, TLBIIPAS2L, TLBIIPAS2IS, or TLBIIPAS2LIS instruction is executed in a Secure Privileged mode other than Monitor mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction is executes as if it had been executed in Monitor mode.

For more information about these instructions see *The scope of TLB maintenance instructions* on page G4-3953.

Hyp mode VA to PA address translation instructions

If an ATS1HR or ATS1HW instruction is executed in a Secure Privileged mode other than Monitor mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction is executes as if it had been executed in Monitor mode.

For more information about these instructions see *Address translation instruction naming and operation summary* on page G4-3994.

Stage 1 default memory type

If HCR.DC == 1, then the behavior of the PE when executing in a Non-secure mode other than Hyp mode is consistent with:

- SCTLR.M == 0, regardless of the actual value of SCTLR.M, other than for the value returned by an explicit read of SCTLR.M.
- HCR.VM == 1, regardless of the actual value of HCR.VM, other than for an explicit read of this bit.

Trapping of general exceptions to Hyp mode

Attempting to perform an exception return to a Non-secure PL1 mode when HCR.TGE == 1 invokes an illegal exception return.

Attempting to change from Monitor mode to a Non-secure PL1 mode when HCR.TGE == 1 by executing a CPS or MSR instruction generates an Illegal Execution state exception, by not changing the mode, and setting PSTATE.IL to 1.

When EL3 is using AArch32, attempting to change from a Secure PL1 mode to a Non-secure PL1 mode when HCR.TGE is set, by changing SCR.NS from 0 to 1, results in no change of SCR.NS

Because taking an exception into Non-secure PL1 modes leads to a CONSTRAINED UNPREDICTABLE situation, the following additional properties apply when HCR.TGE == 1:

- All exceptions that would be routed to EL1 are routed to EL2.
- Non-secure SCTLR.M is treated as being 0, regardless of its actual value, other than for an explicit read of of this bit.
- HCR.FMO, HCR.IMO, and HCR.AMO are treated as being 1, regardless of their actual value, other than for an explicit read of these bits.
- All virtual interrupts are disabled.
- Any IMPLEMENTATION DEFINED mechanisms for signalling virtual interrupts are disabled.

Non-Confidential - Beta

Prevention of rootskits using Hyp mode or Secure state

If an HVC instruction is executed in Hyp mode when SCR.HCE == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If an SMC instruction is executed in a Secure privileged mode when SCR.SCD == 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

HVC

For a description of this instruction and the encoding, see *HVC* on page F5-2588.

For the A1 encoding, if `cond field !=1110`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

MSR/MRS Banked registers

Encoding and use of Banked register transfer instructions on page F5-3102 identifies cases where attempted execution of an MRS (Banked register) or MSR (Banked register) was UNPREDICTABLE in ARMv7 and becomes CONSTRAINED UNPREDICTABLE in ARMv8. This includes cases where:

- The target register specified by the {R, SYSm} fields of the instruction encoding is not accessible from the PE mode in which the instruction was executed, see *Usage restrictions on the Banked register transfer instructions* on page F5-3103.
- The instruction was executed specifying unallocated {R, SYSm} field values, see *Encoding the register argument in the Banked register transfer instructions* on page F5-3104.

If one of these encodings for the MSR/MRS (Banked register) instructions is executed, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- An allocated MSR/MRS (Banked register) instruction is executed.

K1.1.31 Reserved values in System and memory-mapped registers and translation table entries

Unless otherwise stated, all unallocated or reserved values of fields with allocated values within the AArch32 System registers, memory-mapped registers, and translation table entries behave in one of the following ways:

- The encoding maps onto any of the allocated values, but otherwise does not cause CONSTRAINED UNPREDICTABLE behavior.
- The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.
- The encoding causes the field to have no functional effect.

Note

These constraints are identical to those for the equivalent AArch64 definitions, as given in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5380.

Non-Confidential - Beta

K1.2 AArch64 CONSTRAINED UNPREDICTABLE behaviors

It contains the following sections:

- *Overview of the constraints on AArch64 UNPREDICTABLE behaviors*.
- *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values*.
- *CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization* on page K1-5369.
- *Translation table base address alignment* on page K1-5369.
- *The Performance Monitors Extension* on page K1-5369.
- *Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED* on page K1-5370.
- *Out of range virtual address* on page K1-5370.
- *Instruction fetches from Device memory* on page K1-5370.
- *Programming the CSSELR_EL1.Level for a cache level that is not implemented* on page K1-5371.
- *Crossing a page boundary with different memory types or Shareability attributes* on page K1-5371.
- *Crossing a peripheral boundary with a Device access* on page K1-5371.
- *CONSTRAINED UNPREDICTABLE behaviors associated with the VTCR_EL2* on page K1-5372.
- *CONSTRAINED UNPREDICTABLE behavior for A64 instructions* on page K1-5372.
- *Out of range values of the Set/Way/Index fields in cache maintenance instructions* on page K1-5380.
- *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5380.
- *Setting the value of EDECR.SS to 1 when not in Debug state* on page K1-5380.
- *CONSTRAINED UNPREDICTABLE behavior in Debug state* on page K1-5380.

K1.2.1 Overview of the constraints on AArch64 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch64 state, the ARMv8-A architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

Note

Software designed to be compatible with the ARMv8-A architecture must not rely on these CONSTRAINED UNPREDICTABLE cases being handled in any way other than those listed under the heading CONSTRAINED UNPREDICTABLE.

K1.2.2 CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values

The ARM architecture allows copies of control values or data values to be cached in a cache or TLB. This can lead to UNPREDICTABLE behavior if the cache or TLB has not been correctly invalidated following a change of the control or data values.

Unless explicitly stated otherwise, the behavior of the PE is consistent with:

- The old data or control value.
- The new data or control value.
- An amalgamation of the control or data values.

Note

This rules applies where inadequate invalidation of the TLB might cause multiple hits within the TLB. In this situation, a failure to invalidate the TLB by code running at a given Privilege level must not make access to regions of memory with permissions or attributes that could not be accessed at that Privilege level possible.

Alternatively, an implementation might generate a Data Abort exception when detecting multiple hits within a TLB, using the TLB Conflict fault code.

The choice between these behaviors might, in some implementations, vary for each use of a control or data value.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

K1.2.3 CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization

The ARM architecture requires that changes to System registers must be synchronized before they take effect. This can lead to UNPREDICTABLE behavior if the synchronization has not been performed.

In these cases, the behavior of the processor is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.

In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.

K1.2.4 Translation table base address alignment

Field [x-1:0] in TTBR0_EL1, TTBR1_EL1, TTBR0_EL2, VTTBR_EL2, or TTBR0_EL3 is RES0. If this field does not have a value of 0, this might result in a misaligned translation table base address. In this case, one of the following behaviors must occur:

- The field that is defined to be RES0 is treated as if all the bits had a value of 0:
  - The value read back might be the value written or it might be 0.
- The calculation of an address for a translation table walk using those registers might be corrupted in those bits that are nonzero.

K1.2.5 The Performance Monitors Extension

The following cases can cause CONSTRAINED UNPREDICTABLE behavior:

- If PMSELR_EL0.SEL is not equal to 31, and PMSELR_EL0.SEL is greater than or equal to PMCR_EL0.N, and the PE is executing in an Exception level in Secure state or in EL2.
- If PMSELR_EL0.SEL is not 31, and PMSELR_EL0.SEL is greater than or equal to MDCR_EL2.HPMN, and the PE is executing in an Exception level in Non-secure state other than in EL2.

In these cases, one of the following behaviors must occur:

- Any access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 from that state is UNDEFINED.
- Any access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 from that state executes as a `NOP`.
- Any access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 from that state either:
  - Ignores writes and returns 0 on reads.
  - Behaves as if PMSELR_EL0.SEL contains an UNKNOWN value that is less than PMCR_EL0.N and the PE is executing in an Exception level in Secure state or in EL2, or behaves as if PMSELR_EL0.SEL contains an UNKNOWN value that is less than MDCR_EL2.HPMN if the PE executing in an Exception level in Non-secure state other than in EL2.

If PMSELR_EL0.SEL is equal to 31, then one of the following behaviors must occur:

- Any access to PMXEVCNTR_EL0 is UNDEFINED.
- Any access to PMXEVCNTR_EL0 executes as a `NOP`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- Any access to PMXEVCNTR_EL0 either:
  - Ignores writes and returns 0 on reads.
  - Behaves as if PMSELR_EL0.SEL contains an UNKNOWN value that is less than PMCR_EL0.N and the PE is executing in an Exception level in Secure state or in EL2, or behaves as if PMSELR_EL0.SEL contains an UNKNOWN value that is less than MDCR_EL2.HPMN if the PE is executing in an Exception level in Non-secure state other than in EL2.

If MDCR_EL2.HPMN is set to 0, or to a value larger than PMCR_EL0.N, then the following CONSTRAINED UNPREDICTABLE behavior applies:

- The value returned by a direct read of MDCR_EL2.HPMN is UNKNOWN.
- Either:
  - An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if MDCR_EL2.HPMN is set to an UNKNOWN non-zero value less than PMCR_EL0.N.
  - All counters are reserved for EL2 use, meaning no counters are accessible from Non-secure EL1 and Non-secure EL0.

K1.2.6 Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED

When a CONSTRAINED UNPREDICTABLE instruction is treated as UNDEFINED, ESR_ELx is UNKNOWN.

Note

The value written to ESR_ELx must be consistent with a value that could be created as the result of an exception from the same Exception level that generated the exception, but was the result of a situation that is not CONSTRAINED UNPREDICTABLE at that Exception level. This is to avoid a possible privilege violation.

K1.2.7 Out of range virtual address

Because of program counter alignment constraints, it is impossible for a PE to fetch an A64 instruction that includes the bytes at virtual address `0xFFFF FFFF FFFF FFFF` and `0x0000 0000 0000 0000`.

If the PE executes a load or store instruction with tagged addressing disabled in the current translation regime, and where the computed virtual address, total access size, and alignment mean that it accesses the bytes at `0xFFFF FFFF FFFF FFFF` and `0x0000 0000 0000 0000`, then the bytes that appear to be from `0x0000 0000 0000 0000` onwards are accessed at an UNKNOWN address.

If the PE executes a load or store instruction with tagged addressing enabled in the current translation regime, and where the computed address, total access size, and alignment mean that it accesses the bytes at `0xFFFF FFFF FFFF FFFF` and `0x0000 0000 0000 0000`, then the bytes that appear to be from `0x0000 0000 0000 0000` onwards are accessed at an UNKNOWN address and the tags associated with address also become UNKNOWN.

K1.2.8 Instruction fetches from Device memory

Instruction fetches from Device memory are CONSTRAINED UNPREDICTABLE.

If a location in memory has the Device attribute and is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location at times when address translation is enabled.

If a branch causes the program counter to point to an area of memory with the Device attribute that is not marked as execute-never for the current Exception level for instruction fetches, then an implementation must perform one of the following behaviors:

- It treats the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
- It generates a Permission fault.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

K1.2.9 Programming the CSSELR_EL1.Level for a cache level that is not implemented

If the CSSELR_EL1.Level is programmed to a cache level that is not implemented, then a read of CSSELR_EL1 returns an UNKNOWN value in CSSELR_EL1.Level.

If the CSSELR_EL1.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR_EL1 an implementation must perform one of the following behaviors:

- The CCSIDR_EL1 read executes as a `NOP`.
- The CCSIDR_EL1 read is UNDEFINED.
- The CCSIDR_EL1 read returns an UNKNOWN value.

K1.2.10 Crossing a page boundary with different memory types or Shareability attributes

A memory access from a load or store instruction that crosses a page boundary to a memory location that has a different memory type or Shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the first address accessed by the instruction.
- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the last address accessed by the instruction.
- Each memory access generated by the instruction uses the memory type and Shareability attribute associated with its own address.
- The instruction generates an Alignment fault caused by the memory type.

  For the Non-secure EL1&0 translation regime:
  - If the stage 1 translation generated the mismatch then the resulting exception is taken to EL1.
  - If the stage 2 translation generated the mismatch then the resulting exception is taken to EL2.
  - If both stages of translation generate the mismatch then the exception can be taken to either EL1 or EL2.
- The instruction executes as a `NOP`.

K1.2.11 Crossing a peripheral boundary with a Device access

Performing memory accesses from one load or store instruction to Device memory that crosses a boundary corresponding to the smallest translation granule size of the implementation causes CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation performs one of the following behaviors:

- All memory accesses generated by the instruction are performed as if the boundary has no effect on the memory accesses.
- All memory accesses generated by the instruction are performed as if the boundary has no effect on the memory accesses except that there is no guarantee of ordering between memory accesses.
- The instruction generates an alignment fault caused by the memory type.

  For the Non-secure EL1&0 translation regime:
  - If the stage 1 translation causes the boundary to be crossed then the resulting exception is taken to EL1.
  - If the stage 2 translation causes the boundary to be crossed then the resulting exception is taken to EL2.
  - If both stages of translation cause the boundary to be crossed then the resulting exception can be taken to either EL1 or EL2.
- The instruction executes as a `NOP`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Note

The boundary referred to is between two Device memory regions that are both:

- Of the size of the smallest implemented translation granule.
- Aligned to the size of the smallest implemented translation granule.

K1.2.12 CONSTRAINED UNPREDICTABLE behaviors associated with the VTCR_EL2

This subsection describes the CONSTRAINED UNPREDICTABLE behavior associated with programming the VTCR_EL2.

If the stage 2 input address size, as programmed in VTCR_EL2.T0SZ, is out of range with respect to the starting level, as programmed in the VTCR_EL2.SL0 field, or the VTCR_EL2.SL0 field is programmed to a reserved value. at the time of a translation walk that uses the stage 2 translation, then a stage 2 level 0 Translation Fault is generated.

K1.2.13 CONSTRAINED UNPREDICTABLE behavior for A64 instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A64 instructions listed in Chapter C6 *A64 Base Instruction Descriptions* and Chapter C7 *A64 Advanced SIMD and Floating-point Instruction Descriptions*.

LDAXP

For a description of this instruction and the encoding, see *LDAXP* on page C6-531.

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

LDNP (SIMD&FP)

For a description of this instruction and the encoding, see *LDNP (SIMD&FP)* on page C7-1042.

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

LDP

For a description of this instruction and the encoding, see *LDP* on page C6-539.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `(t == n || t2 == n) && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

If t == t2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs all of the loads using the specified addressing mode, and the register loaded is set to an UNKNOWN value.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDP (SIMD&FP)

For a description of this instruction and the encoding, see *LDP (SIMD&FP)* on page C7-1044.

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

LDPSW

For a description of this instruction and the encoding, see *LDPSW* on page C6-542.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `(t == n || t2 == n) && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs all of the loads using the specified addressing mode, and the register loaded is set to an UNKNOWN value.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDR (immediate)

For a description of this instruction and the encoding, see *LDR (immediate)* on page C6-545.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRB (immediate)

For a description of this instruction and the encoding, see *LDRB (immediate)* on page C6-552.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

LDRH (immediate)

For a description of this instruction and the encoding, see *LDRH (immediate)* on page C6-556.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRSB (immediate)

For a description of this instruction and the encoding, see *LDRSB (immediate)* on page C6-560.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRSH (immediate)

For a description of this instruction and the encoding, see *LDRSH (immediate)* on page C6-565.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

LDRSW (immediate)

For a description of this instruction and the encoding, see *LDRSW (immediate)* on page C6-570.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDXP

For a description of this instruction and the encoding, see *LDXP* on page C6-593.

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

STP

For a description of this instruction and the encoding, see *STP* on page C6-690.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `(t == n || t2 == n) && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

STLXP

For a description of this instruction and the encoding, see *STLXP* on page C6-679.

CONSTRAINED UNPREDICTABLE behavior

If `s == t || (s == t2)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

If `s == n && n != 31` then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

STLXR

For a description of this instruction and the encoding, see *STLXR* on page C6-682.

CONSTRAINED UNPREDICTABLE behavior

If `s == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If `s == n && n != 31` then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

STLXRB

For a description of this instruction and the encoding, see *STLXRB* on page C6-684.

CONSTRAINED UNPREDICTABLE behavior

If `s == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If `s == n && n != 31` then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

STLXRH

For a description of this instruction and the encoding, see *STLXRH* on page C6-686.

CONSTRAINED UNPREDICTABLE behavior

If `s == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If `s == n && n != 31` then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

STR (immediate)

For a description of this instruction and the encoding, see *STR (immediate)* on page C6-693.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

STRB (immediate)

For a description of this instruction and the encoding, see *STRB (immediate)* on page C6-698.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

STRH (immediate)

For a description of this instruction and the encoding, see *STRH (immediate)* on page C6-702.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

STXP

For a description of this instruction and the encoding, see *STXP* on page C6-713.

CONSTRAINED UNPREDICTABLE behavior

If `s == t || (s == t2)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

If `s == n && n != 31` then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

STXR

For a description of this instruction and the encoding, see *STXR* on page C6-716.

CONSTRAINED UNPREDICTABLE behavior

If `s == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If `s == n && n != 31` then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

STXRB

For a description of this instruction and the encoding, see *STXRB* on page C6-718.

CONSTRAINED UNPREDICTABLE behavior

If `s == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If `s == n && n != 31` then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

STXRH

For a description of this instruction and the encoding, see *STXRH* on page C6-720.

CONSTRAINED UNPREDICTABLE behavior

If `s == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If `s == n && n != 31` then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

K1.2.14 Out of range values of the Set/Way/Index fields in cache maintenance instructions

In the cache maintenance by set/way instructions DC CISW, DC CSW, and DC ISW, if any set/way/index argument is larger than the value supported by the implementation, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

Note

This CONSTRAINED UNPREDICTABLE behavior applies, also, to the AArch32 cache maintenance by set/way instructions DCCISW, DCCSW, and DCISW.

K1.2.15 Reserved values in System and memory-mapped registers and translation table entries

Unless otherwise stated in this manual, all unallocated or reserved values of fields with allocated values within AArch64 System registers, memory-mapped registers, and translation table entries behave in one of the following ways:

- The unallocated value maps onto any of the allocated values, but otherwise does not cause CONSTRAINED UNPREDICTABLE behavior.
- The unallocated value causes effects that could be achieved by a combination of more than one of the allocated values.
- The unallocated value causes the field to have no functional effect.

Note

These constraints are identical to those for the equivalent AArch32 definitions, as given in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5366.

K1.2.16 Setting the value of EDECR.SS to 1 when not in Debug state

The description in *The Halting Step state machine* on page H3-4736 states that software must not set EDECR.SS to 1 unless the PE is in Debug state. If software sets EDECR.SS to 1 when the PE is not in Debug state then behavior is CONSTRAINED UNPREDICTABLE, and one or more of the following behaviors occurs:

- The value of EDECR.SS becomes UNKNOWN.
- The state of the Halting Step state machine becomes UNKNOWN.
- On a reset of the PE, the value of EDECR.SS and the state of the Halting Step state machine are UNKNOWN.

K1.2.17 CONSTRAINED UNPREDICTABLE behavior in Debug state

Behavior in Debug state on page H2-4705 of this manual describes the CONSTRAINED UNPREDICTABLE behaviors that are specifically associated with Debug state.

Appendix K2
Recommended External Debug Interface

This appendix describes the recommended external debug interface. It contains the following sections:

- *About the recommended external debug interface* on page K2-5382.
- *PMUEVENT bus* on page K2-5385.
- *Recommended authentication interface* on page K2-5386.
- *Management registers and CoreSight compliance* on page K2-5387.

Note

This recommended external debug interface specification is not part of the ARM architecture specification. Implementers and users of the ARMv8 architecture must not consider this appendix as a requirement of the architecture. It is included as an appendix to this manual only:

- As reference material for users of ARM products that implement this interface.
- As an example of how an external debug interface might be implemented.

The inclusion of this appendix is no indication of whether any ARM products might, or might not, implement this external debug interface. For details of the implemented external debug interface you must always see the appropriate product documentation.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

K2.1 About the recommended external debug interface

See the *Note* on the first page of this appendix for information about the architectural status of this recommended debug interface.

This specification provides a recommended external debug interface for ARMv8 to define a standard set of connections for validation environments. In general, the connection between components, such as between the PE and Trace extension, is not described here, although the table does include the signals for the CTI connection. Table K2-1 shows the signals in the recommended interface.

Table K2-1 Recommended debug interface signals

Name	Direction	Description	Notes
DBGEN	In	External debug enable	-
SPIDEN	In	Secure privileged external debug enable	-
		Secure privileged self-hosted debug enable	Only in Secure AArch32 modes when enabled by MDCR_EL3.SPD32
NIDEN	In	External profiling and trace enable	-
SPNIDEN	In	Secure external profiling and trace enable	-
EDBGRQ	In	External halt request	Provided for legacy connections only.
DBGACK	Out	External halt request acknowledge	
COMMIRQ	Out	DCC interrupt	Interface to an interrupt controller. See *Interrupt-driven use of the DCC* on page H4-4773 and the pseudocode for function `CheckForDCCInterrupts()` in *Pseudocode description of the operation of the DCC and ITR registers* on page H4-4774.
PMUIRQ	Out	Performance Monitor overflow	Interface to an interrupt controller. See *Behavior on overflow* on page D5-1754.
COMMRX	Out	DTRRX is full	Provided for legacy connection to an interrupt controller only. See *Interrupt-driven use of the DCC* on page H4-4773 and the pseudocode for function `CheckForDCCInterrupts()` in *Pseudocode description of the operation of the DCC and ITR registers* on page H4-4774.
COMMTX	Out	DTRTX is empty	
PMUEVENT[n:0]	Out	Performance Monitors event bus	See *PMUEVENT bus* on page K2-5385.
DBGNOPWRDWN	Out	Core no powerdown request	Interface to a power controller. See DBGPRCR_EL1.CORENPDRQ.
DBGPWRUPREQ	Out	Core powerup request	Interface to a power controller. See EDPRCR.COREPURQ.
DBGRSTREQ	Out	Warm reset request	Interface to a power controller. See EDPRCR.CWRR.
DBGBUSCANCELREQ	Out	All asynchronous entry to Debug state	Extension to the bus interface. See EDRCR.CBRRQ.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Table K2-1 Recommended debug interface signals (continued)

Name	Direction	Description	Notes
DBGPWRDUP	In	Core powerup status	Interface to a power controller. See EDPRSR.PU.
DBGROMADDR[n:12]	In	MDRAR_EL1.ROMADDR	*n* depends on the size of the physical address space.
DBGROMADDRV	In	MDRAR_EL1.Valid	-
PRESETDBG	In	External debug reset	-
CPUPORESET	In	Cold reset	-
CORERESET	In	Warm reset	-
PSELDBG	In	Debug APB slave port	For details see *AMBA APB3*. ARM recommends a single slave port for all integrated debug components. **PADDRDBG31** distinguishes memory-mapped and DAP accesses: **0** Memory-mapped access **1** DAP access
PENABLEDBG	In		
PWRITEDBG	In		
PRDATADBG[31:0]	Out		
PWDATADBG[31:0]	In		
PADDRDBG[n:2][a]	In		
PREADYDBG	Out		
PSLVERRDBG	Out		
PCLKDBG	In		
PCLKENDBG	In		
CTICHIN	In	Asynchronous CoreSight channel interface	For details, see *CoreSight™ v1.0 Architecture Specification*. The ACK signals are not required if the channel interface is synchronous.
CTICHOUTACK	In		
CTICHOUT	Out		
CTICHINACK	Out		
CTIIRQ	Out	CTI interrupt, see *Description and allocation of CTI triggers* on page H5-4783	Implements a handshake for an edge-sensitive interrupt.
CTIIRQACK	In

Table K2-1 Recommended debug interface signals (continued)

Name	Direction	Description	Notes
ATDATA[nx8-1:0]	Out	AMBA 4 ATB interface	For details, see *AMBA 4 ATB Protocol Specification, ATBv1.0 and ATBv1.1*. Only available if the OPTIONAL Trace extension is implemented.
ATBYTES[n-1:0]	Out		
ATID[6:0]	Out		
ATREADY	In		
ATVALID	Out		
AFREADY	Out		
AFVALID	Out		
SYNCREQ	In		
ATCLK	In		
ATCLKEN	In		
ATRESET	In		

a. The value of *n* depends on the size of the address space occupied by the Debug port.

Figure K2-1 shows the recommended debug interface.

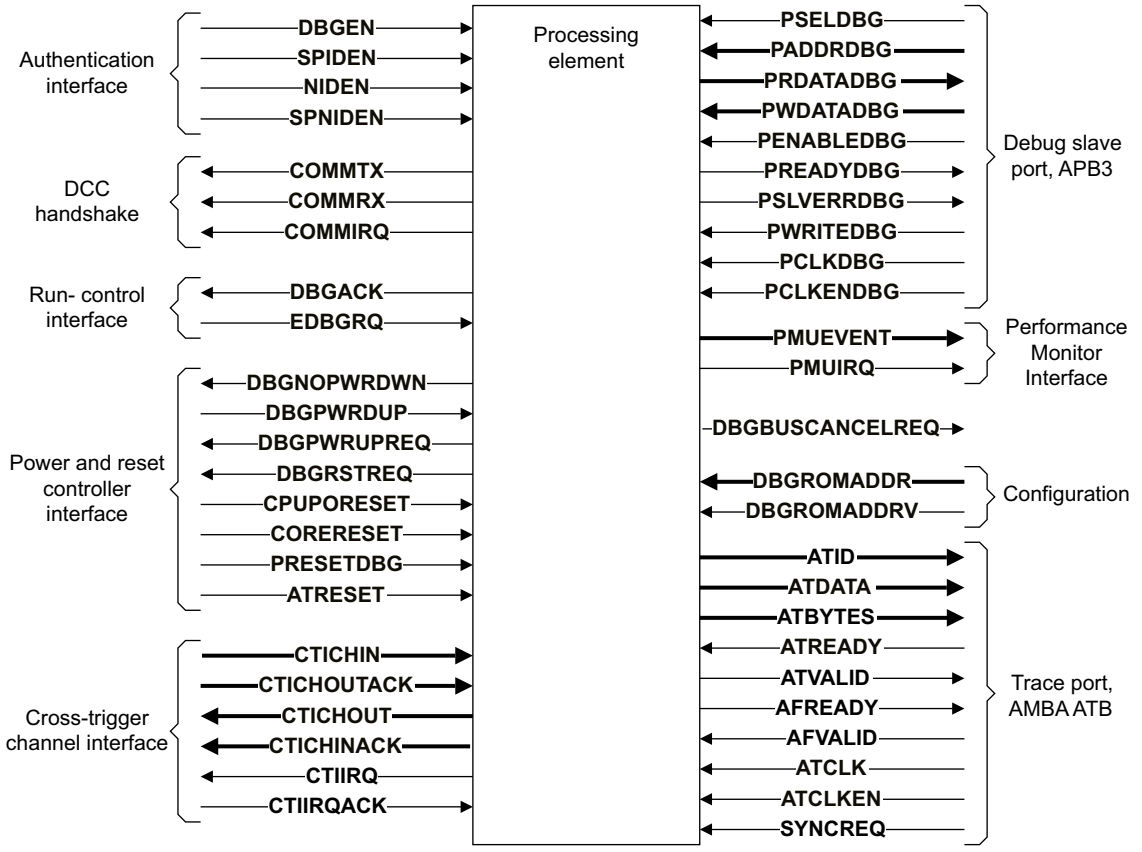

Figure K2-1 Recommended external debug interface, including the APB3 slave port

K2.2 PMUEVENT bus

The **PMUEVENT** bus exports Performance Monitor events from the PE to an on-chip agent. ARM recommends that it has the following characteristics:

- The bus is synchronous.
- The width of the bus is IMPLEMENTATION DEFINED.
- It is IMPLEMENTATION DEFINED which events are exported on the bus.
- Each exported event occupies a contiguous sub-field of the bus. ARM recommends that the sub-fields of the bus are occupied in the same order as the event numbers.
- If the event can only occur once per cycle, it occupies a single bit. If the event can occur more than once per cycle, it is IMPLEMENTATION DEFINED how the event is encoded. The encoding depends on constraints such as the designated use of the event bus and the number of pins available. For example, the event can be encoded:
  - As a count, using a plain binary number. This is the most useful encoding when exporting to an external counter. It is not a useful encoding for exporting to a Trace extension external input.
  - As a count, using thermometer encoding. This is the most useful encoding when exporting to a Trace extension.
  - Using a single bit encoding to indicate whether the event count is zero or nonzero. This is useful for exporting to an activity monitor where the number of pins is constrained.

If a Trace extension is implemented, the **PMUEVENT** bus is normally connected to the Trace extension using the external inputs. TRCEXTINSELR multiplexes a wide **PMUEVENT** bus to a narrow set of inputs. An external **PMUEVENT** bus might also be provided. For more information, contact ARM.

K2.3 Recommended authentication interface

The details of the debug authentication interface are IMPLEMENTATION DEFINED.

ARM recommends the use of the CoreSight interface, which has four signals for external debug authentication:

- **DBGEN**,
- **SPIDEN**.
- **NIDEN**.
- **SPNIDEN**.

CoreSight forbids asserting **SPIDEN** without also asserting **DBGEN**. CoreSight also forbids asserting **SPNIDEN** without also asserting **NIDEN**.

ARM recommends an interface in which **DBGEN** and **SPIDEN** are also used for self-hosted secure debug authentication if either:

- EL3 is using AArch32 and SDCR.SPD == `0b00`.
- Secure EL1 is using AArch32 and MDCR_EL3.SPD32 == `0b00`.

If EL3 is not implemented and the PE is in Non-secure state, **SPIDEN** and **SPNIDEN** are not implemented, and the PE behaves as if these signals were tied LOW.

If EL3 is not implemented and the PE is in Secure state, **SPIDEN** is usually connected to **DBGEN** and **SPNIDEN** is connected to **NIDEN**, but this is not required. The recommended interface is defined as if all four signals are implemented.

How the authentication signals are driven is IMPLEMENTATION DEFINED. For example, the signals might be hard-wired, connected to fuses, or to an authentication module. The architecture permits PEs within a cluster to have independent authentication interfaces, but this is not required. ARM recommends that any Trace extension has the same authentication interface as the PE it is connected to.

Table K2-2 shows the debug authentication pseudocode functions and the recommended implementations.

Table K2-2 Recommended implementation of debug enable pseudocode functions

Pseudocode function	Description	Implementation
`AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled()`	Secure invasive self-hosted debug enabled in AArch32 state (legacy)	(**DBGEN** AND **SPIDEN**)
`ExternalSecureNoninvasiveDebugEnabled()`	Secure non-invasive debug enabled	(**DBGEN** OR **NIDEN**) AND (**SPIDEN** OR **SPNIDEN**)
`ExternalSecureInvasiveDebugEnabled()`	Secure invasive debug enabled	(**DBGEN** AND **SPIDEN**)
`ExternalNoninvasiveDebugEnabled()`	Non-secure non-invasive debug enabled	(**DBGEN** OR **NIDEN**)
`ExternalInvasiveDebugEnabled()`	Non-secure invasive debug enabled	**DBGEN**

The following assertions must apply to all implementations:

- if `!ExternalInvasiveDebugEnabled()` then assert `!ExternalSecureInvasiveDebugEnabled()`.
- if `!ExternalNoninvasiveDebugEnabled()` then assert `!ExternalSecureNoninvasiveDebugEnabled()`.
- if `ExternalInvasiveDebugEnabled()` then assert `ExternalNoninvasiveDebugEnabled()`.
- if `ExternalSecureInvasiveDebugEnabled()` then assert `ExternalSecureNoninvasiveDebugEnabled()`.

The definition for the `Debug_authentication()` function is given in *shared/debug/authentication/Debug_authentication* on page J1-5212.

K2.4 Management registers and CoreSight compliance

The CoreSight architecture requires the implementation of a set of management registers that occupy the memory map from `0xF00` upwards in each of the debug components.

CoreSight compliance and complete implementation of the management registers is OPTIONAL, but ARM recommends that the registers are implemented.

The CoreSight architecture specification recommends that any integration test registers are implemented starting from `0xEFC` downwards. Each of the debug components has an IMPLEMENTATION DEFINED region from `0xE80` to `0xEFC` for this purpose.

K2.4.1 Coresight interface register map

Table K2-3 shows the external management register maps for the following registers:

ED These are the external debug register.

CTI These are the Cross-trigger interface registers.

PMU These are the Performance Monitors registers.

Table K2-3 Coresight interface register map

Offset	Mnemonic			Name
	ED	CTI	PMU	
0xF00	EDITCTRL	CTIITCTRL	PMITCTRL	Integration Model Control registers
0xF04-0xF9C	-	-	-	Reserved, RES0
0xFA0	DBGCLAIMSET_EL1[a]	CTICLAIMSET[b]	-	CLAIM Tag Set registers
0xFA4	DBGCLAIMCLR_EL1[a]	CTICLAIMCLR[b]	-	CLAIM Tag Clear registers
0xFA8	EDDEVAFF0[a]	CTIDEVAFF0[c]	PMDEVAFF0	Device Affinity registers
0xFAC	EDDEVAFF1[a]	CTIDEVAFF1[c]	PMDEVAFF1	
0xFB0	EDLAR[d]	CTILAR[d]	PMLAR[d]	Lock Access register
0xFB4	EDLSR[d]	CTILSR[d]	PMLSR[d]	Lock Status register
0XFB8	DBGAUTHSTATUS_EL1[a]	CTIAUTHSTATUS	PMAUTHSTATUS	Authentication Status register
0xFBC	EDDEVARCH	CTIDEVARCH	PMDEVARCH	Device Architecture register
0xFC0	EDDEVID2[a]	CTIDEVID2[a]	-	Device ID register

Table K2-3 Coresight interface register map (continued)

Offset	Mnemonic			Name
	ED	CTI	PMU	
0xFF0	EDCIDR0	CTICIDR0	PMCIDR0	Component ID registers
0xFF4	EDCIDR1	CTICIDR1	PMCIDR1	
0xFF8	EDCIDR2	CTICIDR2	PMCIDR2	
0xFFC	EDCIDR3	CTICIDR3	PMCIDR3	

a. This register must always be implemented, regardless of whether the component is CoreSight compliant.
b. If implemented, the number of CLAIM bits is IMPLEMENTATION DEFINED and can be discovered by reading CLAIMSET.
c. If the CTI implements CTIv1, this register is not implemented. See the register description for details.
d. The Software lock registers are defined as part of CoreSight compliance, but their contents depend on the type of access that is made and whether the OPTIONAL Software lock is implemented. See the register description for details.

K2.4.2 Management register access permissions

Access to the OPTIONAL Integration Control register (ITCTRL) is IMPLEMENTATION DEFINED.

If the Debug power domain is off, all register accesses return an error.

Otherwise, Table K2-4 on page K2-5389, Table K2-5 on page K2-5390, and Table K2-6 on page K2-5391 show the response to accesses by the external debug interface to the CoreSight management registers. For definitions of the terms used in the tables, see *External debug interface register access permissions summary* on page H8-4819.

Note

Access to the CoreSight management registers is not affected by the values of EDAD and EPMAD.

Table K2-4 on page K2-5389, Table K2-5 on page K2-5390, and Table K2-6 on page K2-5391 include reserved management registers, because the CoreSight architecture requires that these registers are always RES0. The descriptions in *Reserved and unallocated registers* on page H8-4820 does not apply to reserved management registers if the implementation is CoreSight compliant.

If OPTIONAL memory-mapped access to the external debug interface is supported, there are additional constraints on memory-mapped accesses. See *Register access permissions for memory-mapped accesses* on page H8-4816.

The terms in Table K2-4 on page K2-5389, Table K2-5 on page K2-5390, and Table K2-6 on page K2-5391 are defined as follows:

Domain This describes the power domain in which the register is logically implemented. Registers described as implemented in the Core power domain might be implemented in the Debug power domain, as long as they exhibit the required behavior.

Conditions This lists the conditions under which the access is attempted.

To determine the access permissions for a register, read these columns from left to right, and stop at first column which lists the condition as being true.

The conditions are:

Off EDPRSR.PU == 0. The Core power domain is completely off, or in low-power state. In these cases the Core power domain registers cannot be accessed.

Note

If debug power is off, then all external debug interface accesses return an error.

DLK `DoubleLockStatus()` == TRUE. The OS Double Lock is locked.

OSLK OSLSR.OSLK == 1. The OS Lock is locked.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Default This provides the default access permissions, if there are no conditions that prevent access to the register.

SLK This provides the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked. See *Register access permissions for memory-mapped accesses* on page H8-4816. For all other accesses, this column is ignored.

The access permissions are:

- This means that the default access permission applies. See the Default column, or the SLK column, if applicable.

RO This means that the register or field is read-only.

RW This means that the register or field is read/write. Individual fields within the register might be RO. See the relevant register description for details.

RC This means that the bit clears to 0 after a read.

(SE) This means that accesses to this register have indirect write side effects. Aside effect occurs when a direct read or a direct write of a register creates an indirect write to the same register or to another register.

WO This means that the register or field is write-only.

WI This means that the register or field ignores writes.

IMP DEF This means that the access permissions are IMPLEMENTATION DEFINED.

K2.4.3 Management register resets

Table K2-7 shows the management register resets. This table does not include:

- Read-only identification registers that have a fixed value from reset. These registers include those with the DEVAFFn, DEVARCH, DEVID{n}, DEVTYPE, PIDRn, and CIDRn mnemonics.
- Registers that have the AUTHSTATUS mnemonic. This is a read-only status register that reflects the status outside of the reset domain of the register.
- Registers that have the LAR mnemonic. These are write-only registers that only have an effect on writes.

All other fields in the management registers are reset to an IMPLEMENTATION DEFINED value which can be UNKNOWN. The registers are in the reset domain specified in the table.

Table K2-7 shows a summary of the management register resets.

Table K2-7 Management register resets

Register	Reset domain	Field	Value	Description
CTIITCTRL EDITCTRL PMITCTRL	IMPLEMENTATION DEFINED	IME	0	Integration mode enable
DBGCLAIMCLR_EL1	Cold reset	CLAIM	0x00	CLAIM tags
CTICLAIMCLR	External debug	CLAIM	0x00000000

Non-Confidential - Beta

K3.1 ARM recommendations for IMPLEMENTATION DEFINED event numbers

These are the ARM recommendations for the use of the IMPLEMENTATION DEFINED event numbers. ARM does not define these events as rigorously as those in the architectural and microarchitectural event lists, and an implementation might:

- Modify the definition of an event to better correspond to the implementation.
- Not use some, or many, of these event numbers.

Table K3-1 lists the PMU IMPLEMENTATION DEFINED event numbers in event number order.

Table K3-1 PMU IMPLEMENTATION DEFINED event numbers

Event number	Event mnemonic	Description
0x040	L1D_CACHE_RD	Attributable Level 1 data cache access, read
0x041	L1D_CACHE_WR	Attributable Level 1 data cache access, write
0x042	L1D_CACHE_REFILL_RD[a]	Attributable Level 1 data cache refill, read
0x043	L1D_CACHE_REFILL_WR[a]	Attributable Level 1 data cache refill, write
0x044	L1D_CACHE_REFILL_INNER	Attributable Level 1 data cache refill, inner
0x045	L1D_CACHE_REFILL_OUTER	Attributable Level 1 data cache refill, outer
0x046	L1D_CACHE_WB_VICTIM	Attributable Level 1 data cache write-back, victim
0x047	L1D_CACHE_WB_CLEAN	Level 1 data cache write-back, cleaning and coherency
0x048	L1D_CACHE_INVAL	Attributable Level 1 data cache invalidate
0x049-0x04B	-	Reserved
0x04C	L1D_TLB_REFILL_RD[a]	Attributable Level 1 data TLB refill, read
0x04D	L1D_TLB_REFILL_WR[a]	Attributable Level 1 data TLB refill, write
0x04E	L1D_TLB_RD	Attributable Level 1 data or unified TLB access, read
0x04F	L1D_TLB_WR	Attributable Level 1 data or unified TLB access, write
0x050	L2D_CACHE_RD	Attributable Level 2 data cache access, read
0x051	L2D_CACHE_WR	Attributable Level 2 data cache access, write
0x052	L2D_CACHE_REFILL_RD[a]	Attributable Level 2 data cache refill, read
0x053	L2D_CACHE_REFILL_WR[a]	Attributable Level 2 data cache refill, write
0x054-0x055	-	Reserved
0x056	L2D_CACHE_WB_VICTIM	Attributable Level 2 data cache write-back, victim
0x057	L2D_CACHE_WB_CLEAN	Level 2 data cache write-back, cleaning and coherency
0x058	L2D_CACHE_INVAL	Attributable Level 2 data cache invalidate
0x059-0x05B	-	Reserved
0x05C	L2D_TLB_REFILL_RD[a]	Attributable Level 2 data or unified TLB refill, read

0x092-0x09F	-	Reserved
0x0A0	L3D_CACHE_RD	Attributable Level 3 data or unified cache access, read
0x0A1	L3D_CACHE_WR	Attributable Level 3 data or unified cache access, write
0x0A2	L3D_CACHE_REFILL_RD[a]	Attributable Level 3 data or unified cache refill, read
0x0A3	L3D_CACHE_REFILL_WR[a]	Attributable Level 3 data or unified cache refill, write
0x0A4-0x0A5	-	Reserved
0x0A6	L3D_CACHE_WB_VICTIM	Attributable Level 3 data or unified cache write-back, victim
0x0A7	L3D_CACHE_WB_CLEAN	Attributable Level 3 data or unified cache write-back, cache clean
0x0A8	L3D_CACHE_INVAL	Attributable Level 3 data or unified cache access, invalidate

a. For more information, see *Relationship between REFILL events and associated access events* on page K3-5407.

b. In these definitions, an exception that is *taken locally* means an exception that is taken to the default Exception level, and is not routed to another Exception level. See *Exception levels* on page D1-1428 for more information.

0x040, L1D_CACHE_RD, Attributable Level 1 data cache access, read

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

This event is similar to Level 1 data cache access, L1D_CACHE, but the counter counts only memory-read operations that access at least the Level 1 data or unified cache.

0x041, L1D_CACHE_WR, Attributable Level 1 data cache access, write

This event is similar to Level 1 data cache access, L1D_CACHE, but the counter counts only memory-write operations that access at least the Level 1 data or unified cache.

The counter counts DC ZVA as a store instruction.

0x042, L1D_CACHE_REFILL_RD, Attributable Level 1 data cache refill, read

This event is similar to Level 1 data cache refill, L1D_CACHE_REFILL, but the counter counts only memory-read operations that cause a refill of at least the Level 1 data or unified cache.

See also *Relationship between REFILL events and associated access events.* on page K3-5407.

0x043, L1D_CACHE_REFILL_WR, Attributable Level 1 data cache refill, write

This event is similar to Level 1 data cache refill, L1D_CACHE_REFILL, but the counter counts only memory-write operations that cause a refill of at least the Level 1 data or unified cache.

The counter counts DC ZVA as a store instruction.

See also *Relationship between REFILL events and associated access events.* on page K3-5407.

0x044, L1D_CACHE_REFILL_INNER, Attributable Level 1 data cache refill, inner

This event is similar to Level 1 data cache refill, L1D_CACHE_REFILL, but the counter counts only memory-read and memory-write operations that generate refills satisfied by transfer from another cache inside of the immediate cluster.

Note

The boundary between *inner* and *outer* is IMPLEMENTATION DEFINED, and it is not necessarily linked to other similar boundaries, such as the boundary between Inner Cacheable and Outer Cacheable or the boundary between Inner Shareable and Outer Shareable.

0x045, L1D_CACHE_REFILL_OUTER, Attributable Level 1 data cache refill, outer

This event is similar to Level 1 data cache refill, L1D_CACHE_REFILL, but the counter counts only memory-read and memory-write operations that generate refills satisfied from outside of the immediate cluster.

0x046, L1D_CACHE_WB_VICTIM, Attributable Level 1 data cache write-back, victim

This event is similar to Level 1 data cache write-back, L1D_CACHE_WB, but the counter counts only write-backs that are a result of the line being allocated for an access made by the PE.

Write-backs caused by the execution of a cache maintenance instruction are not counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a DC ZVA.

0x047, L1D_CACHE_WB_CLEAN, Level 1 data cache write-back, cleaning and coherency

This event is similar to Attributable Level 1 data cache write-back, L1D_CACHE_WB, but the counter counts only write-backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether write-backs caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.

If a coherency request from a requestor outside the PE results in a write-back, it is an Unattributable event.

Note

The transfer of a dirty cache line from the Level 1 data cache of this PE to the Level 1 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 2 cache or memory.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

0x048, L1D_CACHE_INVAL, Attributable Level 1 data cache invalidate

The counter counts each invalidation of a cache line in the Level 1 data or unified cache.

The counter does not count events:

- If a cache refill invalidates a line.
- For locally-executed cache maintenance instructions that operate by set/way.

If a coherency request from a requestor outside the PE results in a write-back, it is an Unattributable event.

0x04C, L1D_TLB_REFILL_RD, Attributable Level 1 data TLB refill, read

This event is similar to Level 1 data TLB refill, L1D_TLB_REFILL, but the counter counts only memory-read operations that cause a data TLB refill of a least the Level 1 data or unified TLB.

See also *Relationship between REFILL events and associated access events.* on page K3-5407.

0x04D, L1D_TLB_REFILL_WR, Attributable Level 1 data TLB refill, write

This event is similar to Level 1 data TLB refill, L1D_TLB_REFILL, but the counter counts only memory-write operations that cause a data TLB refill of a least the Level 1 data or unified TLB.

The counter counts DC ZVA as a store instruction.

See also *Relationship between REFILL events and associated access events.* on page K3-5407.

0x04E, L1D_TLB_RD, Attributable Level 1 data or unified TLB access, read

This event is similar to Level 1 data or unified TLB access, L1D_TLB, but the counter counts only memory-read operations that cause a TLB access to at least the Level 1 data or unified TLB.

0x04F, L1D_TLB_WR, Attributable Level 1 data or unified TLB access, write

This event is similar to Level 1 data or unified TLB access, L1D_TLB, but the counter counts only memory-write operations that cause a TLB access to at least the Level 1 data or unified TLB.

0x050, L2D_CACHE_RD, Attributable Level 2 data cache access, read

This event is similar to Attributable Level 2 data cache access, L2D_CACHE, but the counter counts only memory-read operations that access at least the Level 2 data or unified cache.

0x051, L2D_CACHE_WR, Attributable Level 2 data cache access, write

This event is similar to Attributable Level 2 data cache access, L2D_CACHE, but the counter counts only memory-write operations that access at least the Level 2 data or unified cache.

The counter counts DC ZVA as a store instruction.

0x052, L2D_CACHE_REFILL_RD, Attributable Level 2 data cache refill, read

This event is similar to Attributable Level 2 data cache refill, L2D_CACHE_REFILL, but the counter counts only memory-read operations that cause a refill of at least the Level 2 data or unified cache.

See also *Relationship between REFILL events and associated access events.* on page K3-5407.

0x053, L2D_CACHE_REFILL_WR, Attributable Level 2 data cache refill, write

This event is similar to Attributable Level 2 data cache refill, L2D_CACHE_REFILL, but the counter counts only memory-write operations that cause a refill of at least the Level 2 data or unified cache.

The counter counts DC ZVA as a store instruction.

See also *Relationship between REFILL events and associated access events.* on page K3-5407.

0x056, L2D_CACHE_WB_VICTIM, Attributable Level 2 data cache write-back, victim

This event is similar to Attributable Level 2 data cache write-back, L2D_CACHE_WB, but the counter counts only write-backs that are a result of the line being allocated for an access made by the PE.

Write-backs caused by the execution of a cache maintenance instruction are not counted.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a DC ZVA.

0x057, L2D_CACHE_WB_CLEAN, Level 2 data cache write-back, cleaning and coherency

This event is similar to Attributable Level 2 data cache write-back, L2D_CACHE_WB, but the counter counts only write-backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether write-backs caused by the execution of a cache maintenance instruction are counted as IMPLEMENTATION DEFINED.

Note

The transfer of a dirty cache line from the Level 2 data cache of this PE to the Level 2 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 3 cache or memory.

If a coherency request from a requestor outside the PE results in a write-back, it is an Unattributable event.

0x058, L2D_CACHE_INVAL, Attributable Level 2 data cache invalidate

The counter counts each invalidation of a cache line in the Level 2 data or unified cache.

The counter does not count events:

- If a cache refill invalidates a line.
- For locally executed cache maintenance instructions that operate by set/way.

Note

Software that uses this event must know whether the Level 2 data cache is shared with other PEs. This event does not follow the general rule of Level 2 data cache events of only counting events that directly affect this PE.

If a coherency request from a requestor outside the PE results in a write-back, it is an Unattributable event.

0x05C, L2D_TLB_REFILL_RD, Attributable Level 2 data or unified TLB refill, read

This event is similar to Attributable Level 2 data or unified TLB refill, L2D_TLB_REFILL, but the counter counts only Attributable memory read operations that cause a TLB refill of at least the Level 2 data or unified TLB. See also *Relationship between REFILL events and associated access events.* on page K3-5407.

0x05D, L2D_TLB_REFILL_WR, Attributable Level 2 data or unified TLB refill, write

This event is similar to Attributable Level 2 data or unified TLB refill, L2D_TLB_REFILL, but the counter counts only Attributable memory write operations that cause a TLB refill of at least the Level 2 data or unified TLB. See also *Relationship between REFILL events and associated access events.* on page K3-5407.

0x05E, L2D_TLB_RD, Attributable Level 2 data or unified TLB access, read

This event is similar to Attributable Level 2 data or unified TLB access, L2D_TLB, but the counter counts only Attributable memory read operations that cause a TLB access to at least the Level 2 data or unified TLB.

0x05F, L2D_TLB_WR, Attributable Level 2 data or unified TLB access, write

This event is similar to Attributable Level 2 data or unified TLB access, L2D_TLB, but the counter counts only Attributable memory write operations that cause a TLB access to at least the Level 2 data or unified TLB.

0x060, BUS_ACCESS_RD, Bus access, read

This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read operations that access outside the boundary of the PE and its closely-coupled caches.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

`0x061`**, BUS_ACCESS_WR, Bus access, write**

This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-write operations that access outside the boundary of the PE and its closely-coupled caches.

`0x062`**, BUS_ACCESS_SHARED, Bus access, Normal, Cacheable, Shareable**

This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read and memory-write operations that make Normal, Cacheable, Shareable accesses outside the boundary of the PE and its closely-coupled caches.

Note

It is IMPLEMENTATION DEFINED how the PE translates the attributes from the translation table entry for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.

`0x063`**, BUS_ACCESS_NOT_SHARED, Bus access, not Normal, Cacheable, Shareable**

This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read and memory-write operations that make accesses outside the boundary of the PE and its closely-coupled caches that are not Normal, Cacheable, Shareable. For example, the counter counts accesses marked as:

- Normal, Cacheable, Non-shareable.
- Normal, Non-cacheable.
- Device.

Note

It is IMPLEMENTATION DEFINED, how the PE translates the attributes from the translation table entries for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.

`0x064`**, BUS_ACCESS_NORMAL, Bus access, normal**

This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read and memory-write operations that make Normal accesses outside the boundary of the PE and its closely-coupled caches. For example, the counter counts Normal, Cacheable and Normal, Non-cacheable accesses but does not count Device accesses.

`0x065`**, BUS_ACCESS_PERIPH, Bus access, peripheral**

This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read and memory-write operations that make Device accesses outside the boundary of the PE and its closely-coupled caches.

`0x066`**, MEM_ACCESS_RD, Data memory access, read**

This event is similar to Data memory access, MEM_ACCESS, but the counter counts only memory-read operations that the PE made.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

0x067, MEM_ACCESS_WR, Data memory access, write

This event is similar to Data memory access, MEM_ACCESS, but the counter counts only memory-write operations made by the PE.

0x068, UNALIGNED_LD_SPEC. Unaligned access, read

This event is similar to Data memory access, MEM_ACCESS, but the counter counts only unaligned memory-read operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

0x069, UNALIGNED_ST_SPEC, Unaligned access, write

This event is similar to Data memory access, MEM_ACCESS, but the counter counts only unaligned memory-read operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

0x06A, UNALIGNED_LDST_SPEC, Unaligned access

This event is similar to Data memory access, MEM_ACCESS, but the counter counts only unaligned memory-read operations and unaligned memory-write operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

0x06C, LDREX_SPEC, Exclusive operation speculatively executed, Load-Exclusive

The counter counts Load-Exclusive instructions speculatively executed.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x06D, STREX_PASS_SPEC, Exclusive operation speculatively executed, Store-Exclusive pass

The counter counts Store-Exclusive instructions speculatively executed that completed a write.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the LDREX_SPEC event.

0x06E, STREX_FAIL_SPEC, Exclusive operation speculatively executed, Store-Exclusive fail

The counter counts Store-Exclusive instructions speculatively executed that fail to complete a write. It is within the IMPLEMENTATION DEFINED definition of speculatively executed whether this includes conditional instructions that fail the condition code check.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the LDREX_SPEC event.

0x06F, STREX_SPEC, Exclusive operation speculatively executed, Store-Exclusive

The counter counts Store-Exclusive instructions speculatively executed.

The definition of speculatively executed is IMPLEMENTATION DEFINED but it must be the same as for the LDREX_SPEC event.

ARM recommends that this event is implemented if it is not possible to implement the exclusive operation speculatively executed, Store-Exclusive pass, and exclusive operation speculatively executed, Store-Exclusive fail, events with the same degree of speculation as the LDREX_SPEC event.

0x070, LD_SPEC, Operation speculatively executed, load

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only memory-reading instructions, as defined by the LD_RETIRED event.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

0x071, ST_SPEC, Operation speculatively executed, store

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only memory-writing instructions, as defined by the ST_RETIRED event.

The counter counts DC ZVA as a store operation.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

`0x072`, LDST_SPEC, Operation speculatively executed, load or store

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only memory-reading instructions and memory-writing instructions, as defined by the LD_RETIRED and ST_RETIRED events.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

`0x073`, DP_SPEC, Operation speculatively executed, integer data processing

This event is similar to Operation speculatively executed, INST_SPEC, but counts only integer data-processing instructions. It counts the following operations that operate on the general-purpose registers:

- In AArch64 state, *Data processing - immediate* on page C3-153 and *Data processing - register* on page C3-158.
- In AArch32 state, *Data-processing instructions* on page F1-2288.

This includes `MOV` and `MVN` operations.

This event also counts the following miscellaneous instructions:

- In AArch64 state, *System register instructions* on page C3-140, *System instructions* on page C3-140, and *Hint instructions* on page C3-141.
- In AArch32 state, *PSTATE and banked register access instructions* on page F1-2296, *Banked register access instructions* on page F1-2296, *Miscellaneous instructions* on page F1-2301, other than `ISB` and preloads, and *Coprocessor instructions* on page F1-2303, other than coprocessor load and store instructions.

If the preload instructions `PRFM, PLD`, `PLDW`, and `PLI`, do not count as memory-reading instructions then they must count as integer data-processing instructions.

If `ISB`s do not count as software change of the PC then they must count as integer data-processing instructions.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the INST_SPEC event.

It is IMPLEMENTATION DEFINED whether the following instructions are counted as integer data-processing operations, SIMD operations, or floating-point operations, but ARM recommends that the instructions are all counted as integer data-processing operations:

- For AArch64 state, from the A64 floating-point convert to integer class, operations that move a value between a general-purpose register and a SIMD and floating-point register without type conversion:
  - `FMOV` (general).
- For AArch64 state, from the SIMD Move group, operations that move a values between a general-purpose register and an element or elements in a SIMD and floating-point register:
  - `DUP` (general).
  - `SMOV`.
  - `UMOV`.
  - `INS` (general).
- In AArch32 state:
  - `VDUP` (general-purpose register) and all `VMOV` instructions that transfer data between a general-purpose register and a SIMD and floating-point register.
  - `VMRS`.
  - `VMSR`.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

0x074, ASE_SPEC, Operation speculatively executed, Advanced SIMD

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only Advanced SIMD data-processing instructions, see:

- For AArch64 state, the SIMD operations listed in *Data processing - SIMD and floating-point* on page C3-165.
- For AArch32 state, *Advanced SIMD data-processing instructions* on page F1-2307.

This includes all operations that operate on the SIMD and floating-point registers, except those that are counted as:

- Integer data-processing operations.
- Floating-point data-processing operations.
- Memory-reading operations.
- Memory-writing operations.
- Cryptographic operations other than PMULL, in AArch64 state.
- VMULL, in AArch32 state.

Advanced SIMD scalar operations are counted as Advanced SIMD operations, including those which operate on floating-point values. In AArch64 state, PMULL, and in AArch32 state, VMULL are counted as Advanced SIMD operations.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the INST_SPEC event.

0x075, VFP_SPEC, Operation speculatively executed, floating-point

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only floating-point data-processing instructions, see:

- In AArch64 state, only the scalar floating-point operations listed in *Data processing - SIMD and floating-point* on page C3-165.

  Note

  This event does not count the SIMD floating-point operations listed in *Data processing - SIMD and floating-point* on page C3-165.

- In AArch32 state, *Floating-point data-processing instructions* on page F1-2315.

This includes all operations that operate on the SIMD and floating-point registers as floating-point values, except for SIMD scalar operations and those that are counted as one of:

- Integer data processing.
- Memory-reading operations.
- Memory-writing operations.

The following instructions that take both an integer register and a floating-point register argument and perform a type conversion (to/from integer or to/from fixed-point), are counted as floating-point data-processing operations:

- In AArch64 state, FCVT{<mode>}, UCVTF, and SCVTF.
- In AArch32, VCVT<mode>(floating-point), VCVT, VCVTT, and VCVTB.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the INST_SPEC event.

0x076, PC_WRITE_SPEC, Operation speculatively executed, software change of the PC

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only software changes of the PC. Defined by the instruction architecturally executed, condition code check pass, software change of the PC event, see *Common event numbers* on page D5-1767.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

See also PC_WRITE_RETIRED.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

`0x077`**, CRYPTO_SPEC, Operation speculatively executed, Cryptographic instruction**

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only Cryptographic instructions, except `PMULL` and `VMULL`, see *The Cryptographic Extensions* on page C3-182.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

`0x078`**, BR_IMMED_SPEC, Branch speculatively executed, immediate branch**

The counter counts immediate branch instructions speculatively executed. Defined by the instruction architecturally executed, immediate branch event, see *Common event numbers* on page D5-1767.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

See also BR_IMMED_RETIRED.

`0x079`**, BR_RETURN_SPEC, Branch speculatively executed, procedure return**

The counter counts procedure return instructions speculatively executed. Defined by the BR_RETURN_RETIRED event.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

See also BR_RETURN_RETIRED.

`0x07A`**, BR_INDIRECT_SPEC, Branch speculatively executed, indirect branch**

The counter counts indirect branch instructions speculatively executed. This includes software change of the PC other than exception-generating instructions and immediate branch instructions.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

`0x07C`**, ISB_SPEC, Barrier speculatively executed,** `ISB`

The counter counts instruction synchronization barrier instructions speculatively executed, including CP15ISB.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

`0x07D`**, DSB_SPEC, Barrier speculatively executed,** `DSB`

The counter counts data synchronization barrier instructions speculatively executed, including CP15DSB.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

`0x07E`**, DMB_SPEC, Barrier speculatively executed,** `DMB`

The counter counts data memory barrier instructions speculatively executed, including CP15DSB. It does not include the implied barrier operations of load/store operations with release consistency semantics.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

`0x081`**, EXC_UNDEF, Exception taken, other synchronous**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only synchronous exceptions that are not counted by the other Exception taken events. This event counts only exceptions taken locally.

`0x082`**, EXC_SVC, Exception taken, Supervisor Call**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Supervisor Call exceptions. This event counts only exceptions taken locally.

`0x083`**, EXC_PABORT, Exception taken, Instruction Abort**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Instruction Abort exceptions. This event counts only exceptions taken locally.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

0x084, EXC_DABORT, Exception taken, Data Abort or SError

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Data Abort or SError interrupt exceptions. The counter counts only exceptions taken locally.

0x086, EXC_IRQ, Exception taken, IRQ

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only IRQ exceptions. The counter counts only exceptions taken locally, including Virtual IRQ exceptions.

0x087, EXC_FIQ, Exception taken, FIQ

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only FIQ exceptions. The counter counts only exceptions taken locally, including Virtual FIQ exceptions.

0x088, EXC_SMC, Exception taken, Secure Monitor Call

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Secure Monitor Call exceptions. The counter does not increment on SMC instructions trapped as a Hyp Trap exception.

0x08A, EXC_HVC, Exception taken, Hypervisor Call

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Hypervisor Call exceptions. The counter counts for both Hypervisor Call exceptions taken locally in the hypervisor and those taken as an exception from Non-secure EL1.

0x08B, EXC_TRAP_PABORT, Exception taken, Instruction Abort not taken locally

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Instruction Abort exceptions not taken locally.

0x08C, EXC_TRAP_DABORT, Exception taken, Data Abort or SError not taken locally

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Data Abort or SError interrupt exceptions not taken locally.

0x08D, EXC_TRAP_OTHER, Exception taken, other traps not taken locally

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only those traps that are not counted as:

- Exception taken, Hypervisor Call.
- Exception taken, Instruction Abort not taken locally.
- Exception taken, Data Abort or SError not taken locally.
- Exception taken, IRQ not taken locally.
- Exception taken, FIQ not taken locally.

0x08E, EXC_TRAP_IRQ, Exception taken, IRQ not taken locally

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only IRQ exceptions not taken locally.

0x08F, EXC_TRAP_FIQ, Exception taken, FIQ not taken locally

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only FIQ exceptions not taken locally.

0x090, RC_LD_SPEC, Release consistency operation speculatively executed, Load-Acquire

The counter counts Load-Acquire operations that are speculatively executed. The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x091, RC_ST_SPEC, Release consistency operation speculatively executed, Store-Release

The counter counts Store-Release operations that are speculatively executed. The definition of speculatively executed is IMPLEMENTATION DEFINED.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

0x0A0, L3D_CACHE_RD, Attributable Level 3 data or unified cache access, read

This event is similar to Attributable Level 3 data or unified cache access, L3D_CACHE, but the counter counts only attributable memory read operations that cause a cache access to at least the Level 3 data or unified cache.

0x0A1, L3D_CACHE_WR, Attributable Level 3 data or unified cache access, write

This event is similar to Attributable Level 3 data or unified cache access, L3D_CACHE, but the counter counts only attributable memory write operations that cause a cache access to at least the Level 3 data or unified cache.

0x0A2, L3D_CACHE_REFILL_RD, Attributable Level 3 data or unified cache refill, read

This event is similar to Attributable Level 3 data or unified cache refill, L3D_CACHE_REFILL, but the counter counts only attributable memory read operations that cause a refill of at least the Level 3 data or unified cache from outside the Level 3cache. See also *Relationship between REFILL events and associated access events.* on page K3-5407

0x0A3, L3D_CACHE_REFILL_WR, Attributable Level 3 data or unified cache refill, write

This event is similar to Attributable Level 3 data or unified cache refill, L3D_CACHE_REFILL, but the counter counts only attributable memory write operations that cause a refill of at least the Level 3 data or unified cache from outside the Level 3cache. See also *Relationship between REFILL events and associated access events.* on page K3-5407

0x0A6, L3D_CACHE_WB_VICTIM, Attributable Level 3 data or unified cache write-back, victim

This event is similar to Attributable Level 3 data cache write-back, L3D_CACHE_WB, but the counter counts only write-backs that are a result of the line being allocated for an access made by the PE.

Write-backs caused by the execution of a cache maintenance instruction are not counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a DC ZVA.

0x0A7, L3D_CACHE_WB_CLEAN, Level 3 data or unified cache write-back, cache clean

This event is similar to Attributable Level 3 data cache write-back, L3D_CACHE_WB, but the counter counts only write-backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether write-backs that are caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.

Note

The transfer of a dirty cache line from the Level 3 data cache of this PE to the Level 3 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 3 cache or memory.

If a coherency request from a requestor outside the PE results in a write-back, it is an Unattributable event.

0x0A8, L3D_CACHE_INVAL, Attributable Level 3 data or unified cache access, invalidate

The counter counts each invalidation of a cache line in the Level 3 data or unified cache.

The counter does not count events:

- If a cache refill invalidates a line.
- For locally-executed cache maintenance instructions that operate by set/way.

Note

Software that uses this event must know whether the Level 3 data cache is shared with other PEs. This event does not follow the general rule of Level 3 data cache events of only counting Attributable events.

K3.1.1 Relationship between REFILL events and associated access events.

CACHE_REFILL and TLB_REFILL events count the refills for accesses that are counted by the corresponding CACHE or TLB event. Table K3-2 shows this correspondence.

Table K3-2 Relationship between REFILL events and associated access events

REFILL event	Access event	Ratio REFILL/Access
0x042 L1D_CACHE_REFILL_RD	0x040 L1D_CACHE_RD	Attributable Level 1 cache refill rate, read
0x043 L1D_CACHE_REFILL_WR	0x041 L1D_CACHE_WR	Attributable Level 1 cache refill rate, write
0x04C L1D_TLB_REFILL_RD	0x04E L1D_TLB_RD	Attributable Level 1 TLB refill rate, read
0x04D L1D_TLB_REFILL_WR	0x04F L1D_TLB_WR	Attributable Level 1 TLB refill rate, write
0x052 L2D_CACHE_REFILL_RD	0x050 L2D_CACHE_RD	Attributable Level 2 data cache refill rate, read
0x053 L2D_CACHE_REFILL_WR	0x051 L2D_CACHE_WR	Attributable Level 2 data cache refill rate, write
0x05C L2D_TLB_REFILL_RD	0x05E L2D_TLB_RD	Attributable Level 2 data TLB refill rate, read

Appendix K4
Recommendations for reporting memory attributes on an interconnect

This appendix describes the ARM recommendations for reporting the memory attributes that are assigned by the PE. It contains the following section:

- *ARM recommendations for reporting memory attributes on an interconnect* on page K4-5412.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

K4.1 ARM recommendations for reporting memory attributes on an interconnect

The ARM architecture defines the architectural interface between software and the PE hardware. This means the mechanisms by which different memory type and cacheability attributes are presented on an interface to an interconnect fabric such as AMBA® AXI are, strictly, outside the scope of the architecture. This appendix describes an approach for the interface between a PE implementation and an interconnect fabric that ARM strongly recommends, but these recommendations do not form part of the ARMv8 architecture.

K4.1.1 Effect of microarchitectural choices on memory attributes

Implementations of the ARM architecture permit considerable variability in the presentation of memory attributes on the interconnect fabric, particularly in cases where the PE implementation does not provide optimized support for a memory type. For example, an implementation might treat Write-through locations as Non-cacheable at some level of cache, because functionally this is consistent with the definition of Write-through, but for the particular implementation the performance trade-off does not merit the hardware directly providing Write-through capability. However, in such implementations, the assigned memory attributes are not changed by the microarchitectural choices. The microarchitecture simply implements different ways of handling some memory attributes.

Therefore, ARM strongly recommended that where any or all of the following memory attributes are presented on the interface between a PE and an interconnect fabric, the attributes that are presented are completely consistent with the attributes defined by the translation system:

- The memory type, Normal or Device.
- The Early write acknowledgement attribute.
- The ordering requirements.
- The Shareability.
- The Cacheability, including where practicable, the allocation hints.

Effect when the cache is disabled

ARM also strongly recommends that the effects of the caches being disabled, as described in *Cache enabling and disabling* on page D3-1620 for AArch64 and in *Cache enabling and disabling in AArch32 state* on page G3-3846 for AArch32, are reflected on the interconnect by the memory type and attributes used for memory transactions generated while the cache is disabled.

Appendix K5
ARMv8 Changes to the T32 and A32 Instruction Sets

This appendix summarizes the changes that ARMv8 makes to the T32 and A32 instruction sets. It contains the following sections:

- *The A32 and T32 instruction sets* on page K5-5414.
- *Partial deprecation of IT* on page K5-5415.
- *New A32 and T32 Load-Acquire/Store-Release instructions* on page K5-5416.
- *New A32 and T32 scalar floating-point instructions* on page K5-5417.
- *New A32 and T32 Advanced SIMD floating-point instructions* on page K5-5420.
- *New A32 and T32 instructions provided by the Cryptographic Extension* on page K5-5422.
- *New A32 and T32 System instructions* on page K5-5423.
- *CRC32 instructions* on page K5-5425.

K5.1 The A32 and T32 instruction sets

This chapter describes the changes that ARMv8-A makes to the T32 and A32 instruction sets, compared to an ARMv7-A implementation that includes all of the following extensions:

- Multiprocessing Extensions.
- Large Physical Address Extension.
- Virtualization Extensions.
- Security Extensions.
- VFPv4.
- Advanced SIMDv2.

These ARMv8 changes are not affected by whether the ARMv8-A implementation includes either or both of EL2 and EL3.

ARMv8-A obsoletes the A32 `SWP` and `SWPB` instructions.

ARM deprecates any use of the following instructions. The first two of these deprecations are made for performance reasons. In ARMv8-A, privileged software can disable this functionality, see the descriptions of the SCTLR.{CP15BEN, ITD, SED} and HSCTLR.{CP15BEN, ITD, SED} bits:

- The A32 and T32 CP15 memory barriers CP15DSB, CP15ISB, and CP15DMB.
- A subset of T32 `IT` instruction functionality, as described in *Partial deprecation of IT* on page K5-5415.
- The A32 and T32 `SETEND` instruction.

ARMv8-A adds new A32 and T32 instructions to align with some of the features introduced in the A64 instruction set. These are described in:

- *Partial deprecation of IT* on page K5-5415.
- *New A32 and T32 Load-Acquire/Store-Release instructions* on page K5-5416.
- *New A32 and T32 scalar floating-point instructions* on page K5-5417.
- *New A32 and T32 Advanced SIMD floating-point instructions* on page K5-5420.
- *New A32 and T32 instructions provided by the Cryptographic Extension* on page K5-5422.
- *New A32 and T32 System instructions* on page K5-5423.

Note

The existing A32 and T32 assembler syntax is unchanged from ARMv7 UAL. Where the syntax term <c> is used in this chapter, it represents a standard ARM condition code. Mnemonics that do not include <c> can not be conditionally executed.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

K5.2 Partial deprecation of IT

ARMv8-A deprecates some uses of the T32 IT instruction, for performance reasons. All uses of IT that apply to instructions other than a single subsequent 16-bit instruction from a restricted set are deprecated, as are explicit references to the PC within that single 16-bit instruction. This permits the non-deprecated forms of IT and subsequent instructions to be treated as a single 32-bit conditional instruction. Table K5-1 shows the restricted set of 16-bit instructions that are not deprecated when used in conjunction with IT.

Table K5-1 Non-deprecated IT 16-bit conditional instructions

Permitted 16-bit instructions	Class	Notes
MOV, MVN	Move	Deprecated when Rm or Rd is the PC.
LDR, LDRB, LDRH, LDRSB, LDRSH	Load	Deprecated for PC-relative load literal forms
STR, STRB, STRH	Store	-
ADD, ADC, RSB, SBC, SUB	Add/Subtract	Deprecated for ADD SP,SP,#imm, SUB SP,SP,#imm, and when Rm, Rdn, or Rdm is the PC
CMP, CMN	Compare	Deprecated when Rm or Rn is the PC
MUL	Multiply	-
ASR, LSL, LSR, ROR	Shift	-
AND, BIC, EOR, ORR, TST	Logical	-
BX, BLX	Branch to register	Deprecated when Rm is the PC

The full ARMv7 IT instruction functionality remains available in order to execute legacy T32 code. It is IMPLEMENTATION DEFINED whether an ARMv8 implementation provides an ITD control, that software can use to disable the deprecated uses of the IT instruction. In an implementation that included the ITD control, setting an ITD field to 1 disables the deprecated uses of the IT instruction, making those uses of the IT instruction UNDEFINED. The ITD control fields are:

HSCTLR.ITD When EL2 is using AArch32, makes execution of the deprecated uses of the IT UNDEFINED at EL2.

SCTLR.ITD When EL1 is using AArch32, makes execution of the deprecated uses of the IT UNDEFINED at EL0 and EL1.

SCTLR_EL1.ITD

When EL1 is using AArch64, makes execution of the deprecated uses of the IT UNDEFINED at EL0 when EL0 is using AArch32.

Non-Confidential - Beta

K5.3 New A32 and T32 Load-Acquire/Store-Release instructions

The new Load-Acquire/Store-Release instructions must be naturally aligned. `LDAEXD` and `STLEXD` must be aligned to 8 bytes. An unaligned address causes an alignment fault. For more information about the ordering of Load-Acquire/Store-Release, see *Load-Acquire, Store-Release* on page E2-2254.

K5.3.1 A32 and T32 Load-Acquire/Store-Release (non-exclusive) instructions

Table K5-2 shows the new A32 and T32 Load-Acquire/Store-Release (non-exclusive) instructions.

Table K5-2 A32 and T32 Load-Acquire/Store-Release (non-exclusive) instructions

K5.4 New A32 and T32 scalar floating-point instructions

This section describes the new A32 and T32 scalar floating-point instructions. It contains the following subsections:

- *A32 and T32 floating-point conditional select*.
- *A32 and T32 floating-point minimum and maximum numeric*.
- *A32 and T32 floating-point to integer conversion*.
- *A32 and T32 floating-point conversion between half-precision and double-precision* on page K5-5418.
- *A32 and T32 floating-point round to integer* on page K5-5418.

K5.4.1 A32 and T32 floating-point conditional select

The new `VSEL` instruction conditionally copies one of its two source registers to the destination register. For A32 it provides an alternative to a pair of conditional `VMOV` instructions, while for T32 it compensates for the partial deprecation of `IT` instruction described in *Partial deprecation of IT* on page K5-5415, since it does not require an `IT` prefix.

Table K5-4 shows the A32 and T32 floating-point conditional select instructions

Table K5-4 A32 and T32 Conditional select

Mnemonic	Instruction	See
`VSEL`	Conditional select	*VSELEQ, VSELGE, VSELGT, VSELVS* on page F6-3557

K5.4.2 A32 and T32 floating-point minimum and maximum numeric

The new `VMAXNM` and `VMINNM` instructions implement the `minNum(x,y)` and `maxNum(x,y)` operations defined by the IEEE754-2008 standard. They return the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to `VFP VMAX` and `VMIN`. These instructions cannot be conditionally executed.

Table K5-5 shows the A32 and T32 floating-point minNum and maxNum instructions.

Table K5-5 A32 and T32 floating-point minNum and maxNum instructions

Mnemonic	Instruction	See
`VMAXNM`	Single-precision maxNum (scalar)	*VMAXNM* on page F6-3336
`VMINNM`	Double-precision minNum (scalar)	*VMINNM* on page F6-3343

K5.4.3 A32 and T32 floating-point to integer conversion

These new instructions extend the ARMv7 VFP `VCVT` instructions by providing four additional explicit rounding modes. The instruction syntax is `VCVT`*r*, where *r* selects the rounding mode as follows:

`N` Round to Nearest.

`A` Round to Nearest with Ties to Away.

`P` Round towards Plus Infinity.

`M` Round towards Minus Infinity.

The rounding modes are defined by the IEEE 754 standards, see *Floating-point standards, and terminology* on page A1-48.

These instructions cannot be conditionally executed.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Table K5-6 shows the A32 and T32 FP to integer conversion instructions.

Table K5-6 A32 and T32 floating-point to integer conversion instructions

Mnemonic	Instruction	See
VCVTA	Convert floating-point to integer with Round to Nearest with Ties to Away	*VCVTA (floating-point)* on page F6-3241
VCVTM	Convert floating-point to integer with Round towards Minus Infinity	*VCVTM (floating-point)* on page F6-3248
VCVTN	Convert floating-point to integer with Round to Nearest	*VCVTN (floating-point)* on page F6-3252
VCVTP	Convert floating-point to integer with Round towards Plus Infinity	*VCVTP (floating-point)* on page F6-3256

K5.4.4 A32 and T32 floating-point conversion between half-precision and double-precision

The VFP VCVTT and VCVTB instructions are extended to permit direct conversion between half-precision and double-precision floating-point as a single operation, preventing double rounding errors.

Table K5-7 shows the A32 and T32 instructions to convert between half-precision and double-precision floating-point values.

Table K5-7 A32 and T32 floating-point precision conversion

Mnemonic	Instruction	See
VCVTB	Floating-point convert half-precision to double-precision	*VCVTB* on page F6-3243
VCVTT	Floating-point convert double-precision to half-precision	*VCVTT* on page F6-3261

K5.4.5 A32 and T32 floating-point round to integer

The new round to integer instructions round a floating-point value to the nearest integer floating-point value of the same size. The floating-point exceptions that can be raised by these instructions are the Invalid operation, for a signaling NaN input, or Input Denormal, for a denormal input when flush-to-zero mode is enabled. For VRINTX only an Inexact exception can be raised if the result is numeric and does not have the same numerical value as the source. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal floating-point arithmetic.

The instruction syntax is VRINT*r*, where *r* selects the rounding mode as follows:

- N Round to Nearest.
- A Round to Nearest with Ties to Away.
- P Round towards Plus Infinity.
- M Round towards Minus Infinity.
- Z Round towards Zero.
- R FPSCR rounding mode.
- X FPSCR rounding mode, signaling inexactness.

When *r* is R, X, or Z, the round to integer instruction can be conditionally executed. The remaining round to integer instructions must be unconditional.

Table K5-8 on page K5-5419 shows the A32 and T32 round to integer instructions.

K5.5 New A32 and T32 Advanced SIMD floating-point instructions

The AArch32 Advanced SIMD instructions support only single-precision, 32-bit, floating-point data types, with fixed operating modes of Round to Nearest, Default NaN, and Flush-to-Zero. However, they are extended by the addition of the instructions described in the following subsections:

- *A32 and T32 floating-point minimum and maximum numeric*.
- *A32 and T32 floating-point conversion*.
- *A32 and T32 floating-point round to integral*.

K5.5.1 A32 and T32 floating-point minimum and maximum numeric

Vector forms of the new `VMAXNM` and `VMINNM` instructions are described in *A32 and T32 floating-point minimum and maximum numeric* on page K5-5417.

Table K5-9 shows the A32 and T32 floating-point minNum/maxNum instructions.

Table K5-9 A32 and T32 floating-point minNum/maxNum instructions

Mnemonic	Instruction	See
`VMAXNM`	Single-precision maxNum (vector)	*VMAXNM* on page F6-3336
`VMINNM`	Double-precision minNum (vector)	*VMINNM* on page F6-3343

K5.5.2 A32 and T32 floating-point conversion

Vector forms of the floating-point to integer conversion instructions are described in *A32 and T32 floating-point to integer conversion* on page K5-5417. The instruction syntax is `VCVT`*r*, where *r* selects the rounding mode as follows:

`N` Round to Nearest.

`A` Round to Nearest with Ties to Away.

`P` Round towards Plus Infinity.

`M` Round towards Minus Infinity.

The rounding modes are defined by the IEEE 754 standards, see *Floating-point standards, and terminology* on page A1-48.

Table K5-10 shows the A32 and T32 floating-point conversion instructions.

Table K5-10 A32 and T32 floating-point conversion instructions

`VCVTA`	Vector Convert floating-point to integer with Round to Nearest with Ties to Away	*VCVTA (Advanced SIMD)* on page F6-3239
`VCVTM`	Vector Convert floating-point to integer with Round towards Minus Infinity	*VCVTM (Advanced SIMD)* on page F6-3246
`VCVTN`	Vector Convert floating-point to integer with Round to Nearest	*VCVTN (Advanced SIMD)* on page F6-3250
`VCVTP`	Vector Convert floating-point to integer with Round towards Plus Infinity	*VCVTP (Advanced SIMD)* on page F6-3254

K5.5.3 A32 and T32 floating-point round to integral

Vector forms of the floating-point rounding instructions are described in *A32 and T32 floating-point round to integer* on page K5-5418. The instruction syntax is `VRINT`*r*, where *r* selects the rounding mode as follows:

`N` Round to Nearest.

`A` Round Nearest with Ties to Away.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

`P` Round towards Plus Infinity.

`M` Round towards Minus Infinity.

`Z` Round towards Zero.

`X` Round to Nearest, signaling inexactness.

The rounding modes are defined by the IEEE 754 standards, see *Floating-point standards, and terminology* on page A1-48.

Table K5-11 shows the A32 and T32 floating-point round to integral instructions.

Table K5-11 A32 and T32 SIMD floating-point round to integral instructions

K5.6 New A32 and T32 instructions provided by the Cryptographic Extension

The optional Cryptographic Extension instructions use the SIMD and floating-point register file. For more information see:

- Announcing the Advanced Encryption Standard.
- *The Galois/Counter Mode of Operation*.
- *Announcing the Secure Hash Standard*.

Table K5-12 shows the A32 and T32 Cryptographic Extension instructions.

Table K5-12 A32 and T32 Cryptographic Extension instructions

K5.7 New A32 and T32 System instructions

The section describes the new System instructions. It contains the following subsections:

- *External Debug*.
- *Barriers and hints*.
- *TLB Maintenance*.

K5.7.1 External Debug

Table K5-13 shows the new External Debug support instructions.

Table K5-13 External Debug support instructions

Mnemonic	Instructions	Notes
DCPS1	Debug switch to EL1, valid in Debug state only	-
DCPS2	Debug switch to EL2, valid in Debug state only	-
DCPS3	Debug switch to EL3, valid in Debug state only	-
HLT #uimm6	Halting mode software breakpoint	Enters Debug state if allowed, with a 6-bit payload in uimm6, otherwise treated as UNDEFINED

K5.7.2 Barriers and hints

There are new A32 and T32 barrier options and hint instructions.

Table K5-14 shows the new A32 and T32 barrier instructions.

Table K5-14 Additional barrier instructions

Mnemonic	Notes
DMB {ISHLD, OSHLD, NSHLD, LD}	Data Memory Barrier is extended to support the new Load-Load/Store options
DSB {ISHLD, OSHLD, NSHLD, LD}	Data Synchronization Barrier is extended to support the new Load-Load/Store options
SEVL	Send Event Locally without the requirement to affect other processors, for example to prime a wait-loop that starts with a WFE instructions

K5.7.3 TLB Maintenance

TLB maintenance instructions that are only required to apply to the last level translation table walk of the first stage of translation are added to A32 and T32 as shown in Table K5-15. For more information see *Translation Lookaside Buffers (TLBs)* on page G4-3942 and *TLB maintenance requirements* on page G4-3945.

Table K5-15 Additional A32 and T32 TLB maintenance instructions

Mnemonic	Relation to existing A32/T32 operation
TLBIMVALIS	Related to the TLBIMVAIS operation
TLBIMVAALIS	Related to the TLBIMVAAIS operation
TLBIMVALHIS	Related to the TLBIMVAHIS operation
TLBIMVAL	Related to the TLBIMVA operation

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Table K5-15 Additional A32 and T32 TLB maintenance instructions (continued)

Mnemonic	Relation to existing A32/T32 operation
TLBIMVAAL	Related to the TLBIMVAA operation
TLBIMVALH	Related to the TLBIMVAH operation

A32 and T32 include TLB maintenance instructions that must apply to individual entries from stage 2 TLB structures, that hold IPA to PA translations. These are consistent with the A64 TLBI system instructions described in *New A32 and T32 System instructions* on page K5-5423. The relation between the A32 and T32 instructions and the A64 instructions is shown in Table K5-16.

Table K5-16 Relation of A32 TLB maintenance instructions to A64 instructions

T32 and A32 instruction	Relation to A64 instruction
TLBIIPAS2IS	Equivalent to IPAS2E1IS
TLBIIPAS2LIS	Equivalent to IPAS2LE1IS Related to existing A32/T32 TLBIIPAS2IS operation
TLBIIPAS2	Equivalent to the A64 IPAS2E1 operation
TLBIIPAS2L	Equivalent to IPAS2LE1 operation Related to existing A32/T32 TLBIIPAS2 operation

Note

These new system operations are accessed using the MCR instruction or, if implemented, by an assembler using the SYS mnemonic followed by the TLBI operation name.

Appendix K6
Legacy Instruction Syntax for AArch32 Instruction Sets

This appendix describes the legacy instruction syntax in the ARM instruction sets, and their *Unified Assembler Language* (UAL) equivalents. It contains the following section:

- *Legacy Instruction Syntax* on page K6-5428.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

K6.1 Legacy Instruction Syntax

Early versions of the ARM Architecture defined an assembly language for A32 (ARM) instructions, and a separate assembly language for T32 (Thumb) instructions. UAL is based on the A32 assembly language, with some changes to the instruction syntax. The appendix describes those changes. The pre-UAL mnemonics are compatible with UAL, and might be supported by an assembler.

The original T32 assembly language is not compatible with UAL, and is not described in the manual.

K6.1.1 Pre-UAL instruction syntax for the A32 base instructions

Table K6-1 lists the syntax for the A32 base instructions that have changed after UAL was introduced.

Table K6-1 Pre-UAL instruction syntax f or the A32 base instructions

K6.1.3 FCONST

The syntax of FCONST is

```
FCONST<dest>{<c>} <Fd>, #<imm8>
```

where:

<dest> Specifies the destination data type. It must be one of:

- S . Single-precision floating-point.
- D . Double-precision floating-point.

<c> This is an optional field. It specifies the condition under which the instruction is executed. See *Conditional execution* on page F2-2323 for the range of available conditions and their encoding. If <c> is omitted, it defaults to *always* (AL).

<Fd> Specifies the destination register. It must be one of:

- <Dd> 64-bit name of the SIMD&FP destination register.
- <Sd> 32-bit name of the SMID&FP destination register.

<imm8> Specifies the immediate value used to generate the floating-point constant.

`FCONSTD{<c>} <Dd>, #<imm8>` maps to `VMOV.F64 <Dd>, #<fpimm>`

`FCONSTS{<c>} <Sd>, #<imm8>` maps to `VMOV.F32 <Sd>, #<fpimm>`

Address translation examples

This appendix gives examples of address translations using the translation regimes described in Chapter D4 *The AArch64 Virtual Memory System Architecture* and Chapter G4 *The AArch32 Virtual Memory System Architecture*. It contains the following sections:

- *AArch64 Address translation examples* on page K7-5436.
- *AArch32 Address translation examples* on page K7-5449.

Note

This chapter gives examples of translation table lookups for the ARMv8 address translation stages. It does not define any part of the address translation mechanism. If any information in this appendix appears to contradict the information in Chapter D4 *The AArch64 Virtual Memory System Architecture* or Chapter G4 *The AArch32 Virtual Memory System Architecture* then the information in Chapter D4 or Chapter G4 must be taken as the definition of the required behavior.

K7.1 AArch64 Address translation examples

Figure D4-2 on page D4-1650 shows the VMSAv8 address translation stages that are controlled by an Exception level that is using AArch64. *The VMSAv8-64 address translation system* on page D4-1649 describes the VMSAv8-64 address translation scheme. This section gives examples of the use of that scheme, for common translation requirements.

System registers relevant to MMU operation on page D4-1654 specifies the relevant registers, including the TCR and TTBR, or TTBRs, for each stage of address translation.

For any stage of translation, a TCR.T*n*SZ field indicates the supported input address size. For a stage of address translation controlled from an Exception level using AArch64, the supported input address size is $2^{(64-T\mathit{n}SZ)}$.

This section describes:

- Performing the initial lookup, for an address for which the initial lookup is either:
  - At the highest lookup level used for the appropriate translation granule size.
  - Because of the concatenation of translation tables at the initial lookup level, one level down from the highest level used for the translation granule size.

  These descriptions take account of the following cases:
  - The IA size is smaller than the largest size for the translation level, see *Reduced IA width* on page D4-1662.
  - For a stage 2 translation, translation tables are concatenated, to move the initial lookup level down by one level, see *Concatenated translation tables* on page D4-1663.

  For examples of performing the initial lookup, see *Examples of performing the initial lookup*.
- The full translation flow for resolving a page of memory. These examples describe resolving the largest IA size supported by the initial lookup level. For these examples, see *Full translation flows for VMSAv8-64 address translation* on page K7-5443.

K7.1.1 Examples of performing the initial lookup

The address ranges used for the initial translation table lookup depend on the translation granule, as described in:

- *Performing the initial lookup using the 4KB translation granule*.
- *Performing the initial lookup using the 16KB granule* on page K7-5439.
- *Performing the initial lookup using the 64KB translation granule* on page K7-5441.

Performing the initial lookup using the 4KB translation granule

This subsection describes examples of the initial lookup when using the 4KB translation granule that Table D4-12 on page D4-1668 shows as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in *The VMSAv8-64 address translation system* on page D4-1649.

Note

For stage 2 translations, the same principles apply to an initial lookup that Table D4-12 on page D4-1668 shows as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.

The following subsections describe these examples of the initial lookup:

- *Initial lookup at level 0, 4KB translation granule* on page K7-5437.
- *Initial lookup at level 1, 4KB translation granule* on page K7-5437.

In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see *Overview of stage 2 translations, 4KB granule* on page D4-1667.

Non-Confidential - Beta

Initial lookup at level 0, 4KB translation granule

This subsection describes initial lookups with an input address width of (n+1) bits, meaning the input address is IA[n:0]. As Table D4-12 on page D4-1668 shows, a stage 1 or stage 2 initial lookup at level 0 is required when $39 \le n \le 47$. For these lookups:

- TTBR[47:(n-35)] specify the translation table base address.
- Bits[n:39] of the input address are bits[(n-36):3] of the descriptor offset in the translation table.

Note

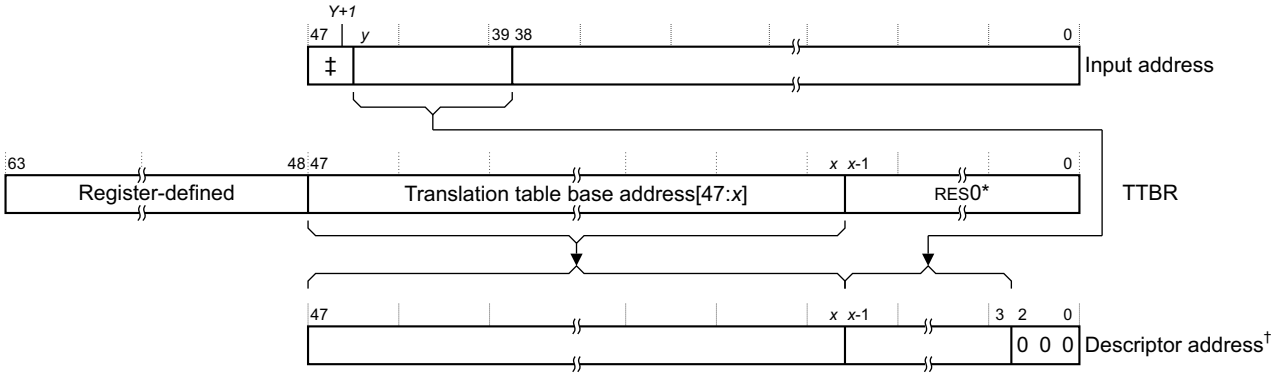
This means that, when the input address width is less than 48 bits

- The size of the translation table is reduced.
- More low-order bits of the TTBR are required to specify the translation table base address.
- Fewer input address bit are used to specify the descriptor offset in the translation table.

For example, if the input address width is 46 bits:

- The translation table size is 1KB,
- TTBR bits[47:10] specify the translation table base address.
- Input address bits[45:39] specify bits[9:3] of the descriptor offset.

Figure K7-1 shows this lookup.



Supported input address range is IA[y:0], $4 \le x \le 12$, $y = x + 35$. When y is 47 the field marked ‡ is absent.
† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.
* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-1 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 0

Initial lookup at level 1, 4KB translation granule

This subsection describes initial lookups with an input address width of (n+1) bits, meaning the input address is IA[n:0].

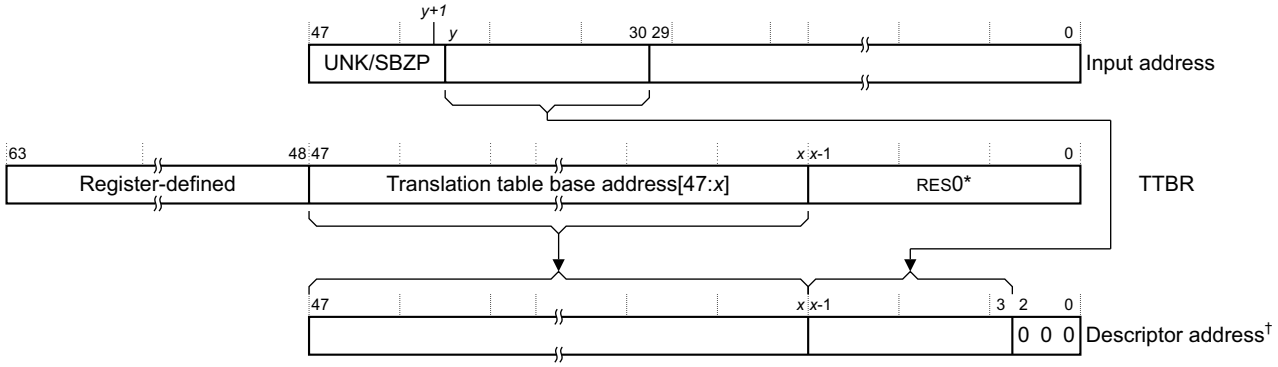
For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables

As Table D4-12 on page D4-1668 shows, this applies to IA[n:0], where $30 \le n \le 38$. For these lookups:

- There is a single translation table at this level.
- TTBR[47:(n-26)] specify the translation table base address.
- Bits[n:30] of the input address are bits[(n-27):3] of the descriptor offset in the translation table.

Figure K7-2 on page K7-5438 shows this lookup.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



Supported input address range is IA[*y*:0], 4 ≤ *x* ≤ 12, *y* = *x* + 26.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

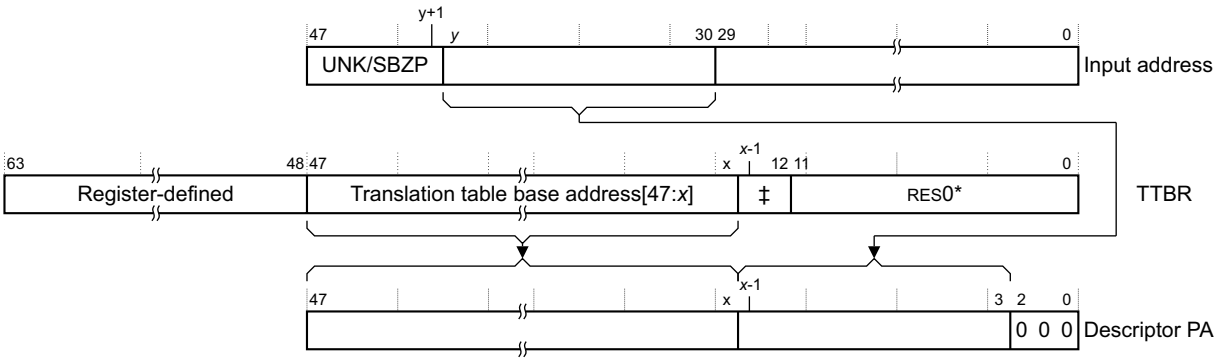
Figure K7-2 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 1, without concatenation

For a stage 2 initial lookup at level 1, with concatenated translation tables

As Table D4-12 on page D4-1668 shows, this applies to IA[*n*:0], where 39 ≤ *n* ≤ 42. For these lookups:

- There are $2^{(n-38)}$ concatenated translation tables at this level.
- These concatenated translation tables must be aligned to $2^{(n-38)}$×4KB. This means TTBR[(*n*-27):12] must be zero.
- TTBR[47:(*n*-26)] specify the base address of the block of concatenated translation tables.
- Bits[*n*:30] of the input address are bits[(*n*-27):3] of the descriptor offset from the base address of the block of concatenated translation tables.

Figure K7-3 shows this lookup.



Supported input address range is IPA[*y*:0], 4 ≤ *x* ≤ 16, *y* = *x* + 26. The field marked ‡ must be zero.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-3 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 1, with concatenation

Performing the initial lookup using the 16KB granule

This subsection describes examples of the initial lookup when using the 16KB translation granule that Table D4-15 on page D4-1671 shows as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in *The VMSAv8-64 address translation system* on page D4-1649.

Note

For stage 2 translations, the same principles apply to an initial lookup that Table D4-15 on page D4-1671 shows as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.

The following subsections describe these examples of the initial lookup:

- *Initial lookup at level 0, 16KB translation granule*.
- *Initial lookup at level 1, 16KB translation granule* on page K7-5440.

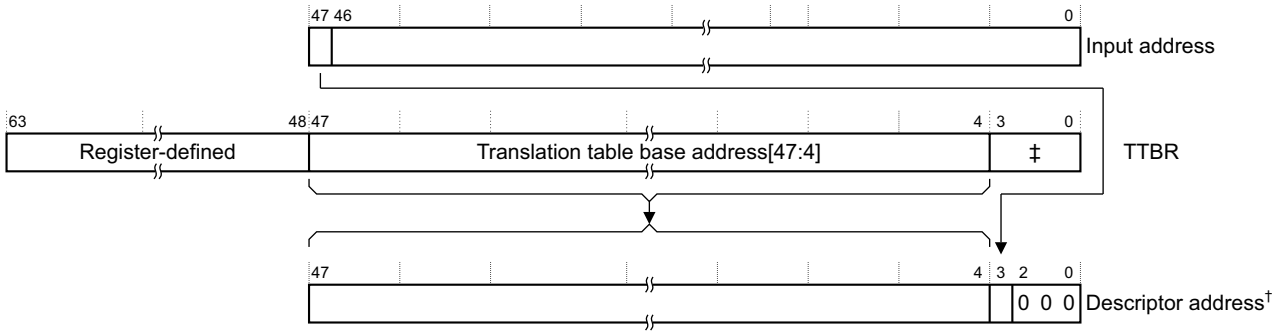
In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see *Overview of stage 2 translations, 16KB granule* on page D4-1671.

Initial lookup at level 0, 16KB translation granule

This subsection describes initial lookups with an input address width of (n+1) bits, meaning the input address is IA[n:0]. As Table D4-14 on page D4-1670 shows, the only case where an address translation using the 16KB granule starts at level 0 is a stage 1 translation of a 48-bit input address, IA[47:0]. For this lookup:

- The required translation table has only two entries, meaning its size is 16bytes, and it must be aligned to 16 bytes.
- TTBR[47:4] specify the translation table base address.
- Bit[47] of the input address is bits[3] of the descriptor offset in the translation table.

Figure K7-4 shows this lookup.



Supported input address range is IA[47:0]. The field marked ‡ is RES0*.
† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.
* Field has additional properties to the default RES0 definition, see the register description for more information.

Non-Confidential - Beta

Initial lookup at level 1, 16KB translation granule

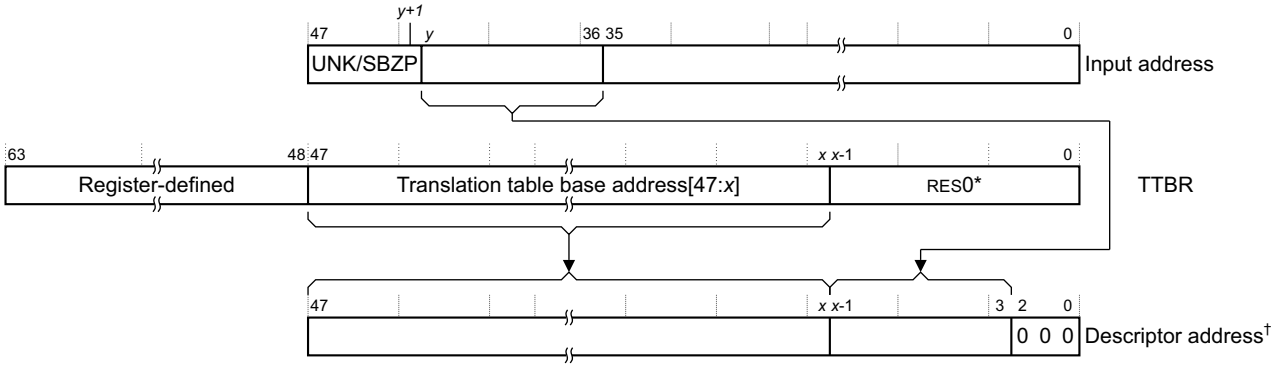
This subsection describes initial lookups with an input address width of (n+1) bits, meaning the input address is IA[n:0].

For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables

As Table D4-15 on page D4-1671 shows, this applies to IA[n:0], where $36 \le n \le 46$. For these lookups:

- There is a single translation table at this level.
- TTBR[47:(n-32)] specify the translation table base address.
- Bits[n:36] of the input address are bits[(n-33):3] of the descriptor offset in the translation table.

Figure K7-5 shows this lookup.



Supported input address range is IA[y:0], $4 \le x \le 14$, $y = x + 32$.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-5 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 1, without concatenation

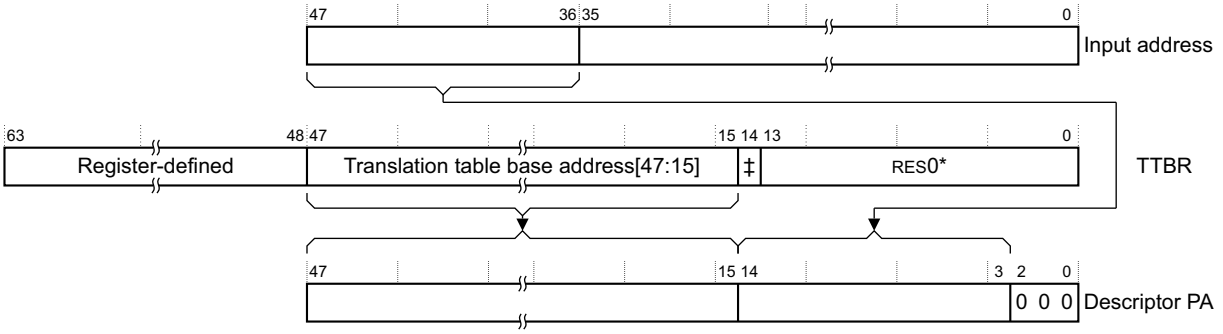
For a stage 2 initial lookup at level 1, with concatenated translation tables

As Table D4-15 on page D4-1671 shows, the only case where an address translation using the 16KB granule starts at level 1 because of concatenation of translation tables is a stage 2 translation of a 48-bit input address, IA[47:0]. For this lookup:

- There are two concatenated translation tables at this level.
- These concatenated translation tables must be aligned to 2×16KB. This means TTBR[14] must be zero.
- TTBR[47:15] specify the base address of the block of two concatenated translation tables.
- Bits[47:36] of the input address are bits[14:3] of the descriptor offset from the base address of the block of concatenated translation tables.

Figure K7-6 on page K7-5441 shows this lookup.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



Supported input address range is IPA[47:0]. The bit marked ‡ must be zero.
* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-6 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 1, with concatenation

Performing the initial lookup using the 64KB translation granule

This subsection describes examples of the initial lookup when using the 64KB translation granule that Table D4-18 on page D4-1674 shows as starting at level 1 or at level 2. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 2. This means that it gives specific examples of the mechanisms described in *The VMSAv8-64 address translation system* on page D4-1649.

Note

For stage 2 translations, the same principles apply to an initial lookup that Table D4-18 on page D4-1674 shows as starting at level 2. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 3.

The following subsections describe these examples of the initial lookup:

- *Initial lookup at level 1, 64KB translation granule*.
- *Initial lookup at level 2, 64KB translation granule* on page K7-5442.

In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see *Overview of stage 2 translations, 64KB granule* on page D4-1674.

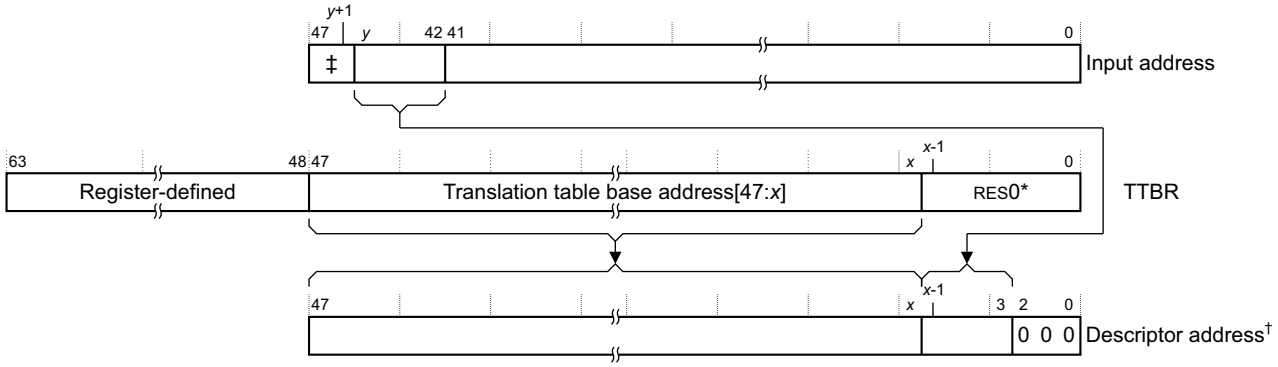
Initial lookup at level 1, 64KB translation granule

This subsection describes initial lookups with an input address width of (n+1) bits, meaning the input address is IA[n:0]. As Table D4-18 on page D4-1674 shows, a stage 1 or stage 2 initial lookup at level 1 is required when $42 \le n \le 47$. For these lookups:

- The size of the translation table is $2^{(n-39)}$ bytes. This means the size of the translation table, at this level, is always less than the granule size. The address of this translation table must align to the size of the table.
- Bits[n:42] of the input address are bits[(n-39):3] of the descriptor offset in the translation table.
- Bits[47:(n-38)] of the TTBR specify the translation table base address.

Figure K7-7 on page K7-5442 shows this lookup.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta



Supported input address range is IA[*y*:0], 4 ≤ *x* ≤ 9, *y* = *x* + 38. When *y* is 47 the field marked ‡ is absent.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-7 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 1

Initial lookup at level 2, 64KB translation granule

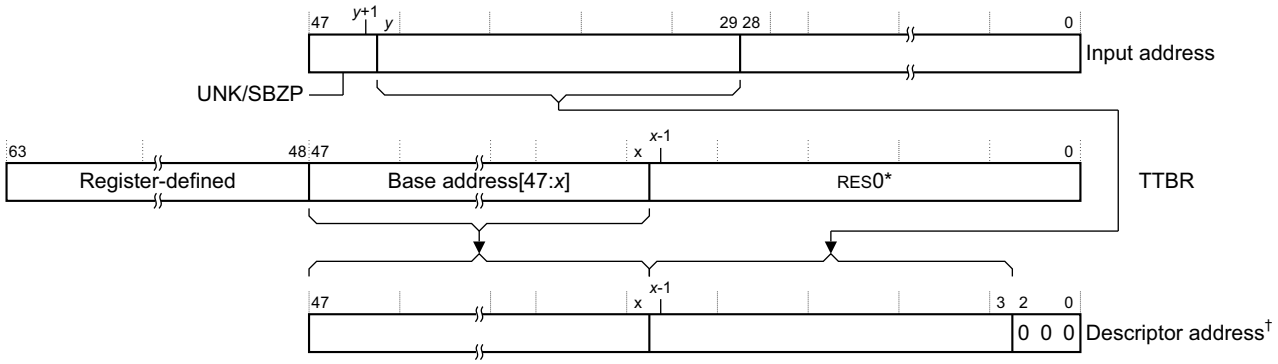
This subsection describes initial lookups with an input address width of (*n*+1) bits, meaning the input address is IA[*n*:0].

For a stage 1 or stage 2 initial lookup at level 2, without the use of concatenated translation tables

As Table D4-18 on page D4-1674 shows, this applies to IA[*n*:0], where 29 ≤ *n* ≤ 41. For these lookups:

- There is a single translation table at this level.
- TTBR[47:(*n*-25)] of the specify the translation table base address.
- Bits[*n*:29] of the input address are bits[(*n*-26):3] of the descriptor offset in the translation table.

Figure K7-8 shows this lookup.



Supported input address range is IA[*y*:0]. 4 ≤ *x* ≤ 16, *y* = *x* + 25.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-8 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, without concatenation

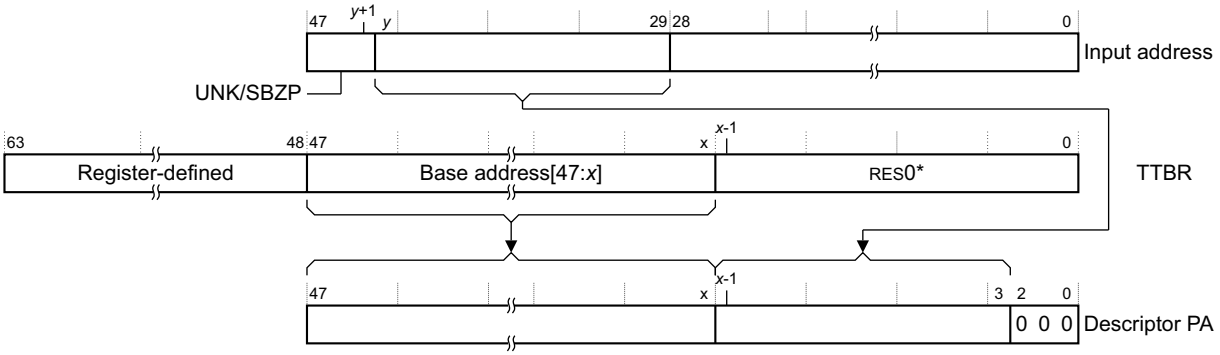
Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

For a stage 2 initial lookup at level 2, with concatenated translation tables

As Table D4-18 on page D4-1674 shows, this applies to IA[n:0], where $42 \le n \le 45$. For these lookups:

- There are $2^{(m-41)}$ concatenated translation tables at this level.
- These concatenated translation tables must be aligned to $2^{(m-41)} \times 64$KB. This means TTBR[(n-26):16] must be zero.
- TTBR[47:(n-25)] specify the base address of the block of translation tables.
- Bits[n:42] of the input address are bits[(n-26):16] of the descriptor offset from the base address of the block of translation tables.

Figure K7-9 shows this lookup.



Supported input address range is IPA[y:0], $4 \le x \le 20$, $y = x + 25$.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-9 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, with concatenation

K7.1.2 Full translation flows for VMSAv8-64 address translation

In a translation table walk, only the first lookup uses the translation table base address from the appropriate TTBR. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

This section describes example full translation flows, from the initial lookup to the address of a memory page. The example flows:

- Resolve the maximum-sized IA range supported by the initial lookup level.
- Do not have any concatenation of translation tables.
- Cover only the 4KB and the 64KB translation granules.

Examples of performing the initial lookup on page K7-5436 described how either reducing the IA range or concatenating translation tables affects the initial lookup.

Note

Reducing the IA range or concatenating translation tables affects only the initial lookup.

The following sections describe full VMSAv8-64 translation flows, down to an entry for a memory page:

- *The address and properties fields shown in the translation flows* on page K7-5444.
- *Full translation flow using the 4KB granule and starting at level 0* on page K7-5445.
- *Full translation flow using the 4KB granule and starting at level 1* on page K7-5446.
- *Full translation flow using the 64KB granule and starting at level 1* on page K7-5447.
- *Full translation flow using the 64KB granule and starting at level 2* on page K7-5448.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

The address and properties fields shown in the translation flows

For the Non-secure EL1&0 stage 1 translation:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the block or page.

In these cases, an EL1&0 stage 2 translation is performed to translate the IPA to the required PA.

For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see *Memory attribute fields in the VMSAv8-64 translation table format descriptors* on page D4-1697.

Non-Confidential - Beta

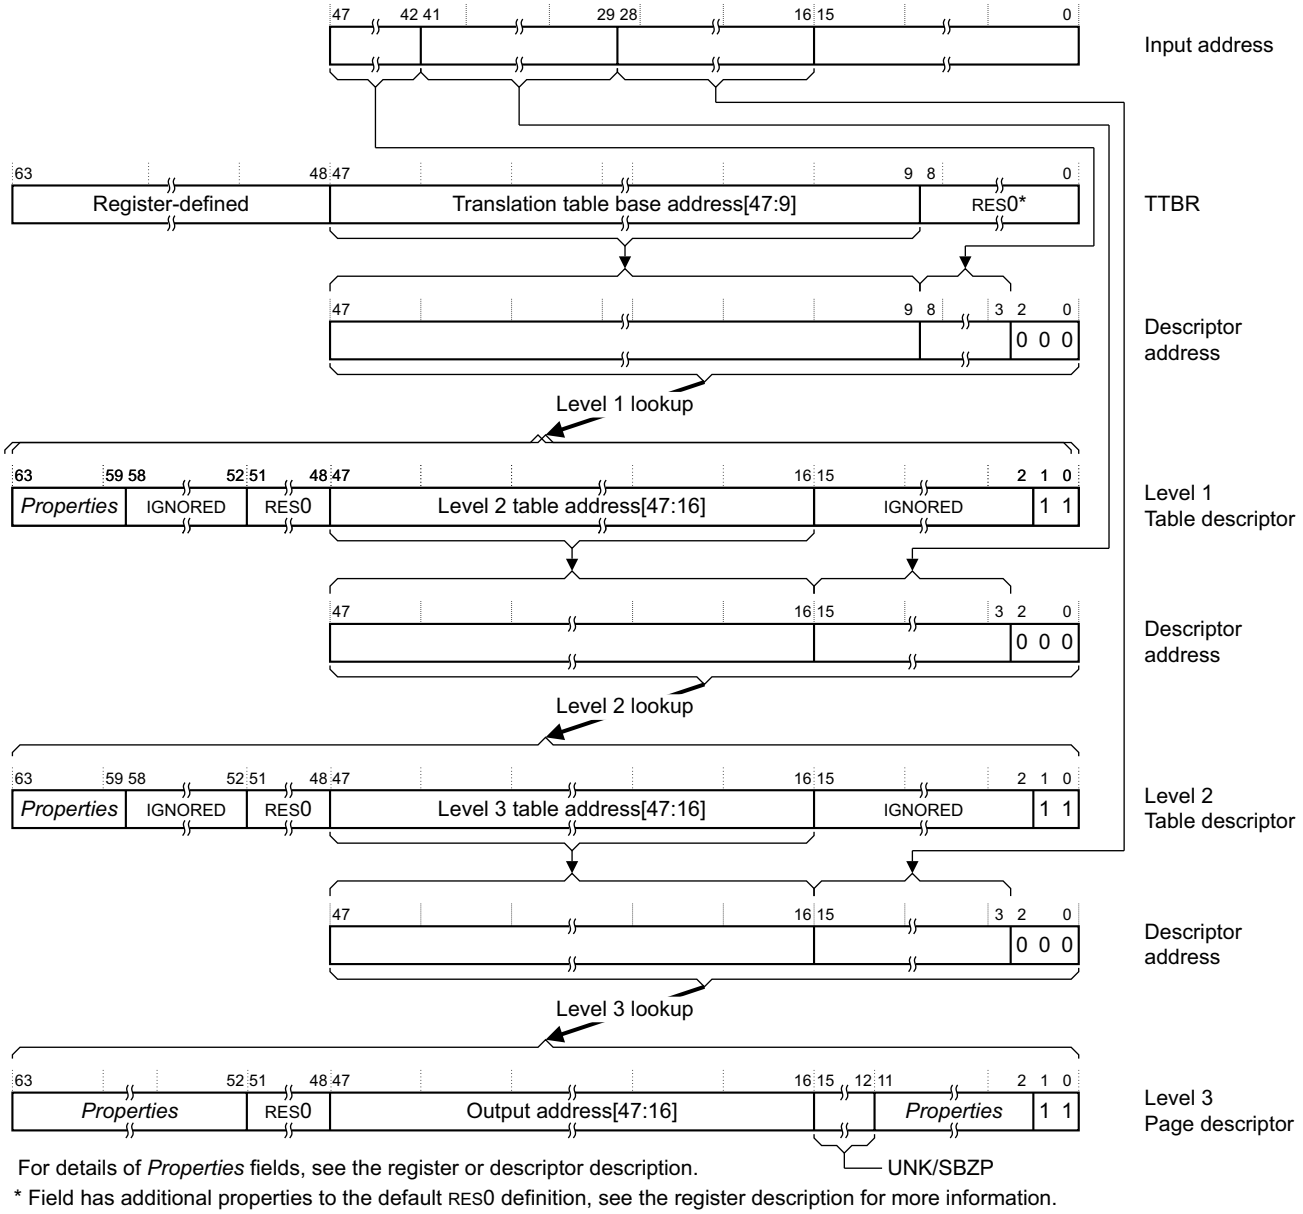
Figure K7-11 on page K7-5446 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in Figure K7-10 on page K7-5445, shows how the translation for the 42-bit address start the same lookup process one stage later.

Full translation flow using the 64KB granule and starting at level 1

Figure K7-10 on page K7-5445 shows the complete translation flow for a stage 1 translation table walk for a 48-bit input address. This lookup must start with a level 0 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows* on page K7-5444.



For details of *Properties* fields, see the register or descriptor description.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-12 Complete stage 1 translation of a 48-bit address using the 64KB translation granule

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K7-12 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

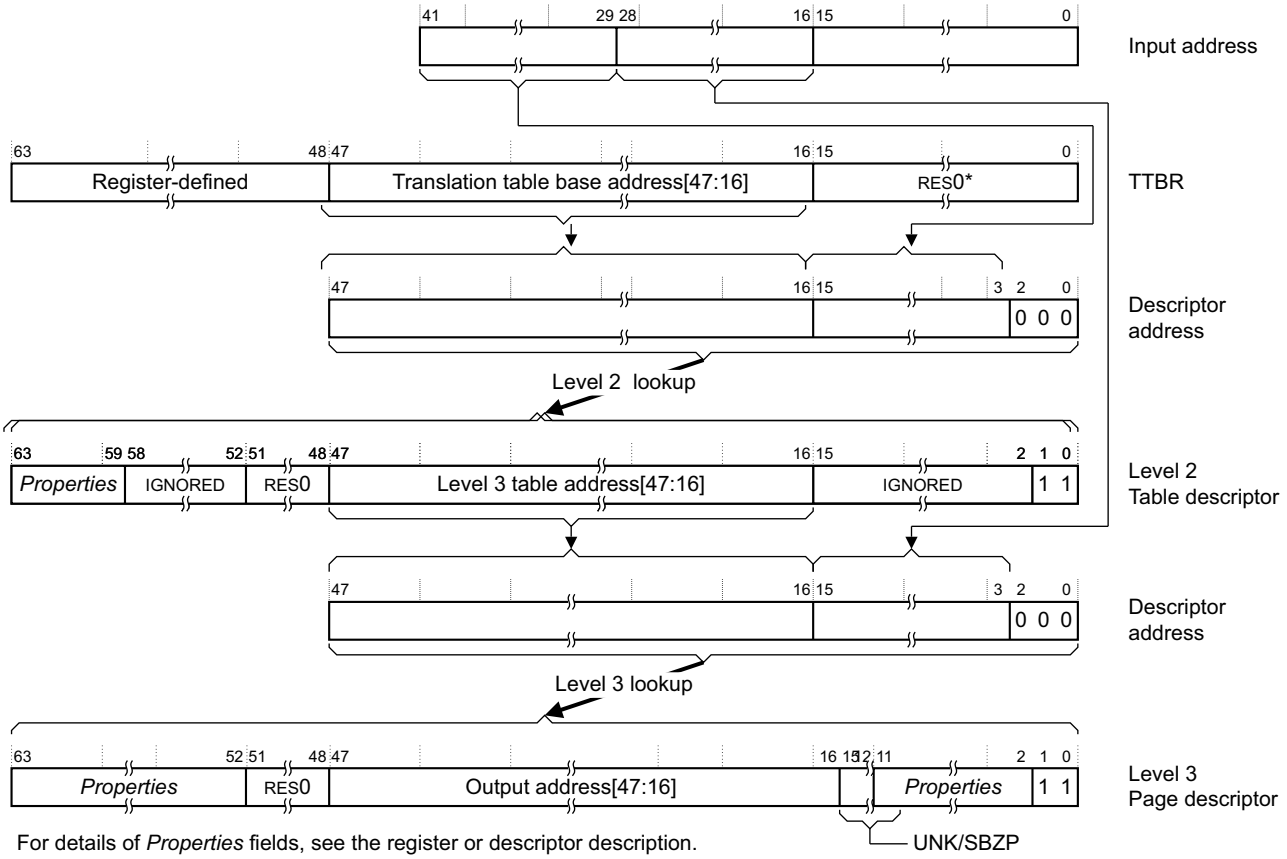
Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

The level 1 lookup resolves only 6 bits of the input address. As described in *Performing the initial lookup using the 64KB translation granule* on page K7-5441, this means:

- The translation table size for this level is only 512 bytes.
- The required translation table alignment for this level is 512 bytes.
- The Base address field in the TTBR is extended, at the low-order end, to be bits[47:9].

Full translation flow using the 64KB granule and starting at level 2

Figure K7-11 on page K7-5446 shows the complete translation flow for a stage 1 translation table walk for a 42-bit input address. This lookup must start with a level 2 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows* on page K7-5444.



For details of *Properties* fields, see the register or descriptor description.
* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-13 Complete stage 1 translation of a 42-bit address using the 64KB translation granule

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K7-13 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in Figure K7-12 on page K7-5447, shows:

- The translation for the 42-bit address starts the same lookup process one stage later.
- Because the initial lookup resolves 13 bits of address:
  - The translation table size for this level is 64KB.
  - The required translation table alignment for this level is 64KB.
  - The Base address field in the TTBR is bits[47:16].

The address and Properties fields shown in the translation flows

For the Non-secure PL1&0 stage 1 translation tables:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the Section, Supersection, Large page, or Small page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.

Otherwise, the address is the PA of the descriptor, Section, Supersection, Large page, or Small page.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see *Information returned by a translation table lookup* on page G4-3889, and the description of the register or translation table descriptor.

For translations using the Short-descriptor translation table format, *VMSAv8-32 Short-descriptor translation table format descriptors* on page G4-3894 describes the descriptors formats.

K7.2.2 Address translation examples using the VMSAv8-32 Long descriptor translation table format

As described in *Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format* on page G4-3916, in a translation table walk, only the first lookup uses the translation table base address from the appropriate TTBR. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

The following sections give examples of full VMSAv8-32 Long-descriptor format address translation flows, down to an entry for a 4KB page:

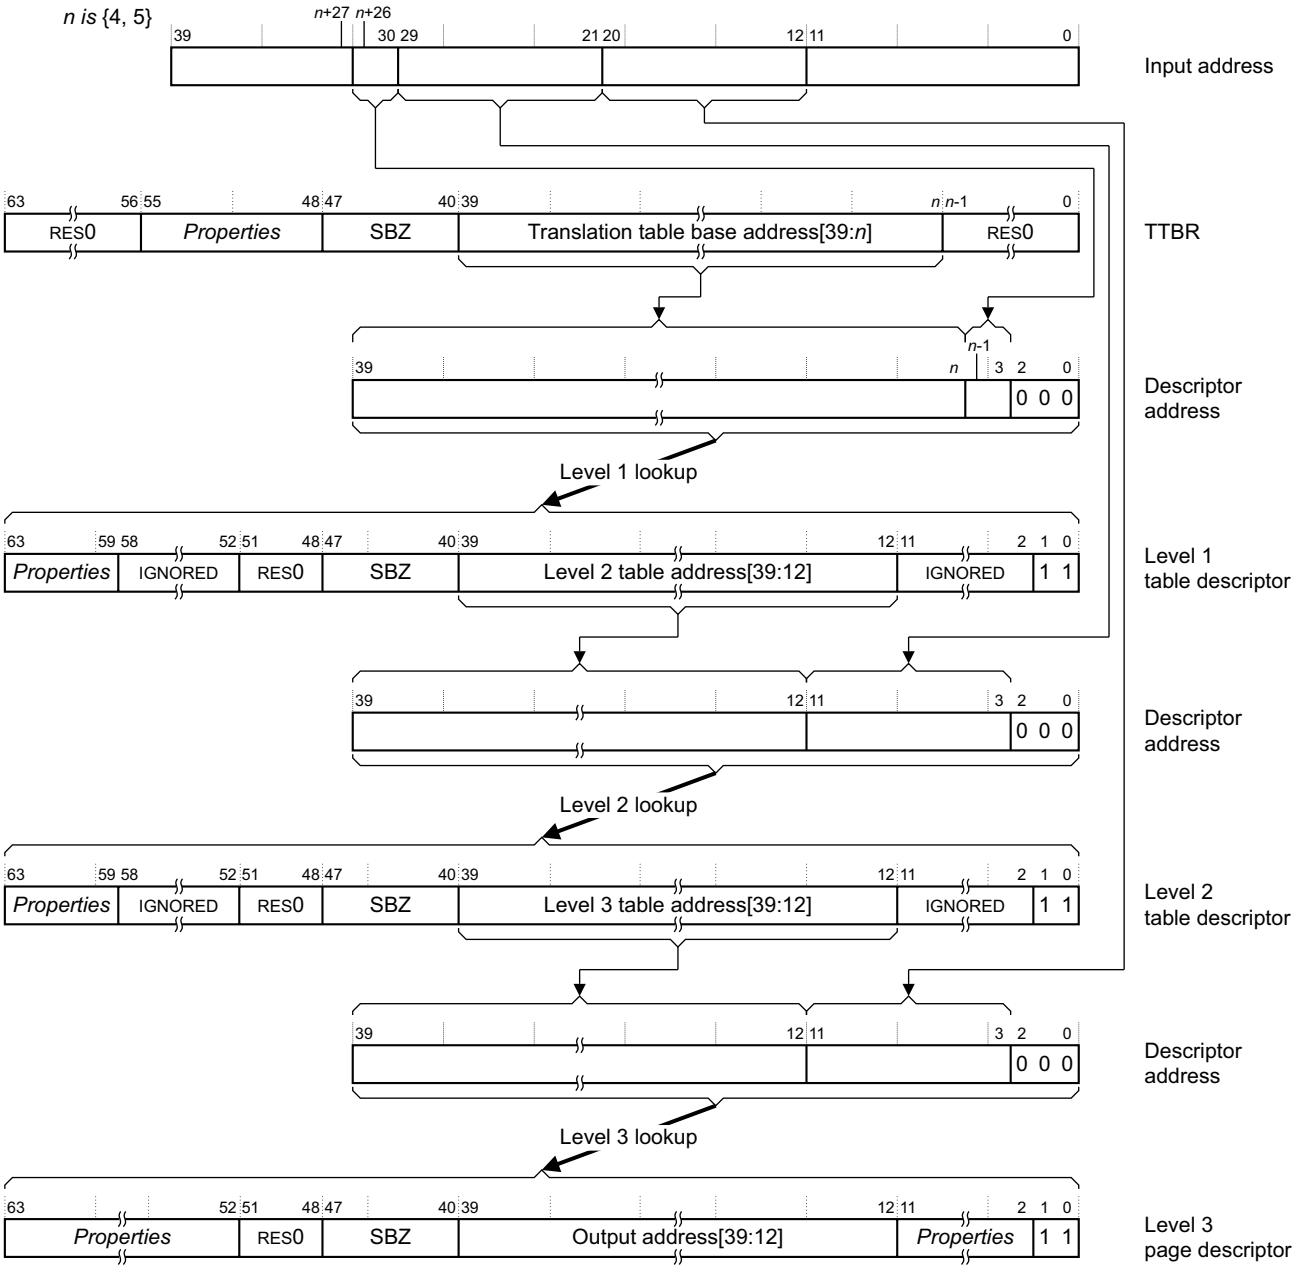
- *Full translation flow, starting at level 1 lookup* on page K7-5455.
- *Full translation flow, starting at level 2 lookup* on page K7-5456.

The address and Properties fields shown in the translation flows summarizes the information returned by the lookup.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Full translation flow, starting at level 1 lookup

Figure K7-18 shows the complete translation flow for a VMSAv8-32 Long-descriptor stage 1 translation table walk that starts with a level 1 lookup. For more information about the fields shown in the figure see *The address and Properties fields shown in the translation flows* on page K7-5454.



For details of *Properties* fields, see the register or descriptor description.

Figure K7-18 Complete VMSAv8-32 Long-descriptor format stage 1 translation, starting at level 1

If the level 1 lookup or the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

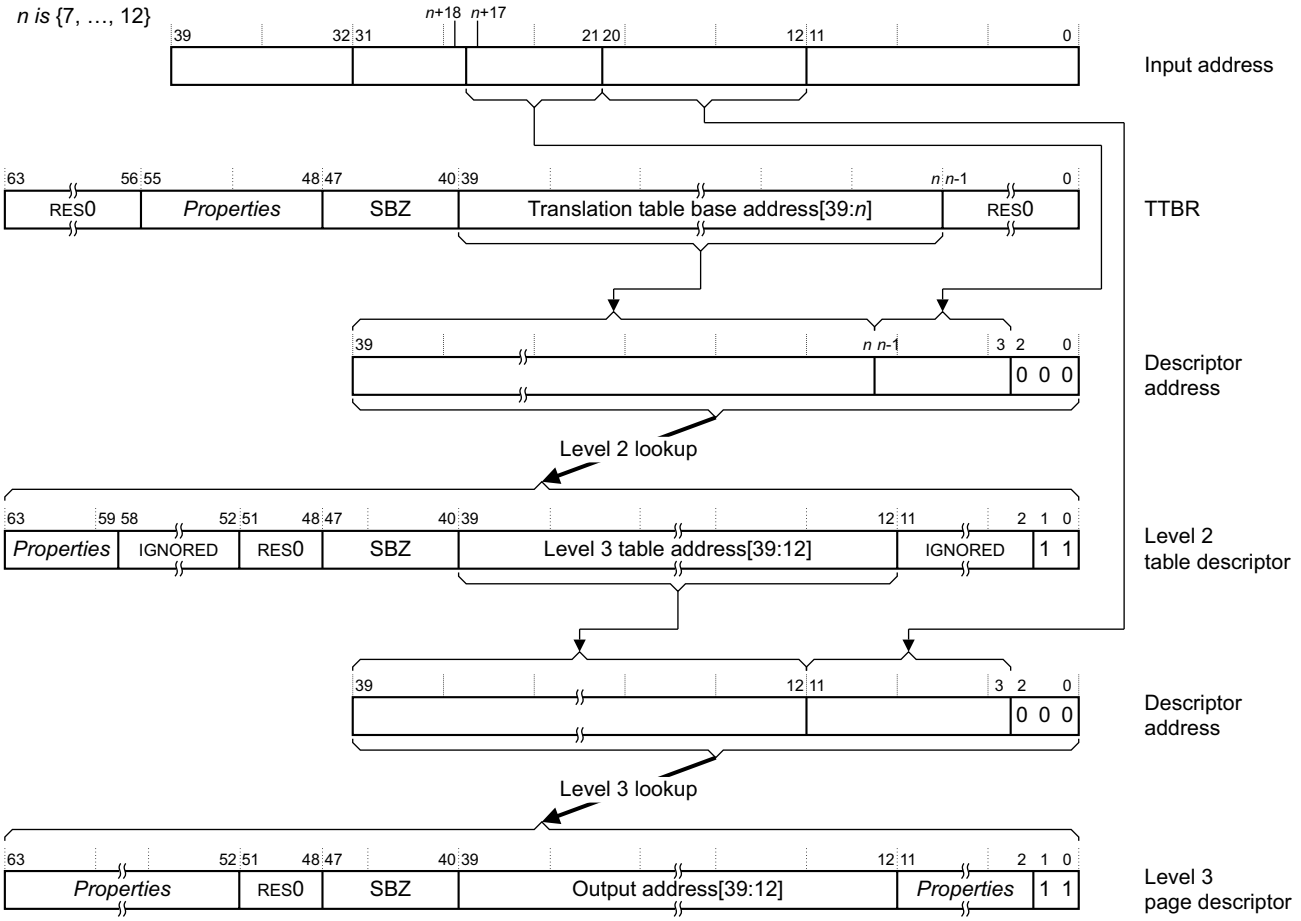
Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

A stage 2 translation that starts at a level 1 lookup differs from the translation shown in Figure K7-18 on page K7-5455 only as follows:

- The possible values of *n* are 4-13, to support an input address of between 31 and 40 bits.
- A descriptor and output addresses are always PAs.

Full translation flow, starting at level 2 lookup

Figure K7-19 shows the complete translation flow for a stage 1 VMSAv8-32 Long-descriptor translation table walk that starts at a level 2 lookup. For more information about the fields shown in the figure see *The address and Properties fields shown in the translation flows* on page K7-5454.



For details of *Properties* fields, see the register or descriptor description.

Figure K7-19 Complete VMSAv8-32 Long-descriptor format stage 1 translation, starting at level 2

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

A stage 2 translation that starts at a level 2 lookup differs from the translation shown in Figure K7-19 only as follows:

- The possible values of *n* are 7-16, to support an input address of up to 34 bits.
- The descriptor and output addresses are always PAs.

The address and Properties fields shown in the translation flows

For the Non-secure PL1&0 stage 1 translation:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the block or page.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.

For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see *Information returned by a translation table lookup* on page G4-3889, and the description of the register or translation table descriptor.

For translations using the Long-descriptor translation table format, *VMSAv8-32 Long-descriptor translation table format descriptors* on page G4-3903 describes the descriptors formats.

Appendix K9
Recommended Upload and Download Processes for External Debug

This appendix contains the following section:

- *Using memory access mode in AArch64 state* on page K9-5466.

Note

This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might find this information useful.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

K9.1 Using memory access mode in AArch64 state

Figure K9-1 and Figure K9-2 on page K9-5467 show the processes for using memory access mode to implement a download (external host to target) and an upload (target to external host).

To transfer *n* words of data:

- The download sequence needs *n*+6 accesses by the external debug interface.
- The upload sequence needs *n*+8 accesses by the external debug interface.

In both cases, in the innermost loop the debugger can make an external access to a DTR without polling EDSCR after each write as underrun and overrun detection prevent failure. Normally external accesses from the debugger are outpaced by the memory accesses of the PE, making underruns and overruns unlikely. If this is not the case, the EDSCR.ERR flag is set to 1. This is checked once at the end of the sequence, although a debugger can check it more often, for example once for each page. If the EDSCR.ERR flag is set to 1 because of overrun or underrun, the debugger can restart. The address to restart from is frozen in X0. EDSCR.ERR might also be set because of a Data abort.

If underruns and overruns are common, the debugger can pace itself accordingly.

Note

- The base address must be a multiple of 4.
- The order of the writes that set up the address does not matter in Debug state.

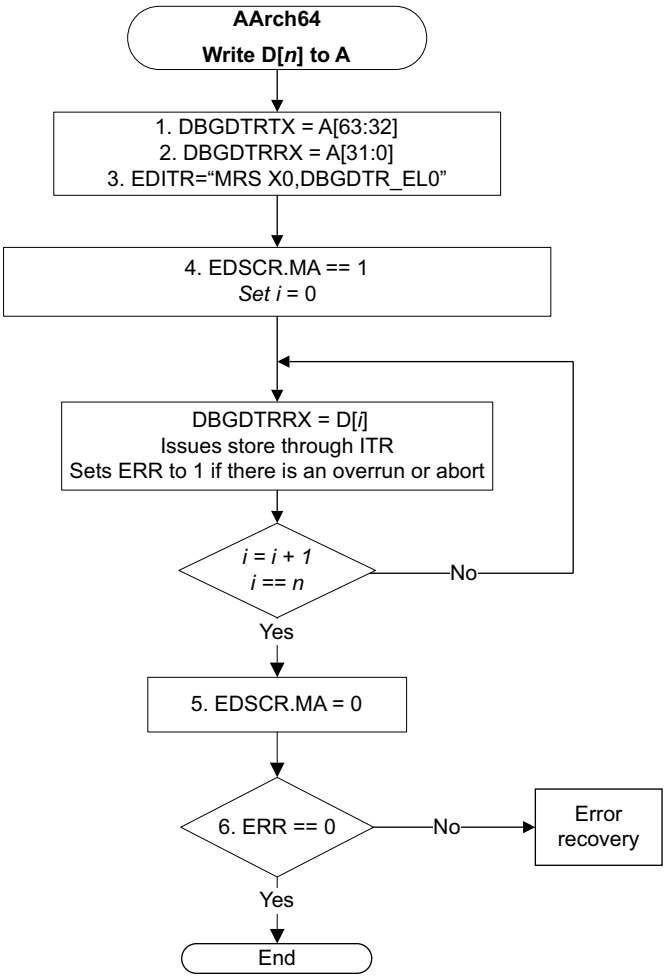

Figure K9-1 Fast code download in AArch64 (external host to target)

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

In Figure K9-1 on page K9-5466, the sequence for the fast code download is as follows:

1. Setup. From the external debug interface:
   a. Write address [31:0] to DBGDTRRX_EL0.
   b. Write address [63:32] to DBGDTRTX_EL0.
   c. Write `MRS X0, DBGDTR_EL0` to EDITR. The PE executes this instruction.
   d. Set EDSCR.MA to 1.
2. Loop *n* times. From the external debug interface:
   a. Write to DBGDTRRX_EL0. The PE reads the word from DTRRX and stores it to memory. It increments X0 by 4.
3. Epilogue. From the external debug interface:
   a. Clear EDSCR.MA to 0.
   b. Read EDSCR to check for overruns or Data Aborts during download.

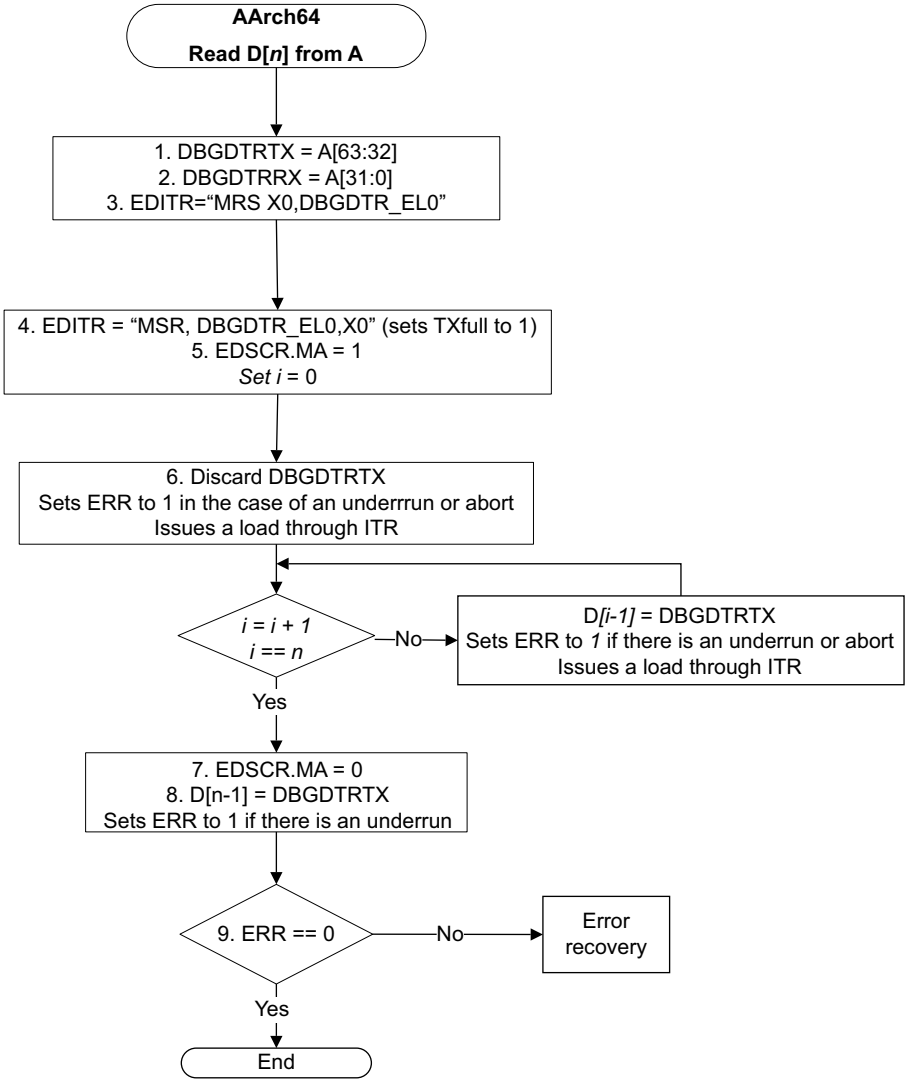

Figure K9-2 Fast data upload in AArch64 (target to external host)

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

In Figure K9-2 on page K9-5467, the sequence for the fast code download is as follows:

1. Setup. From the external debug interface:
   a. Write address [31:0] to DBGDTRRX_EL0.
   b. Write address [63:32] to DBGDTRTX_EL0.
   c. Write `MRS X0, DBGDTR_EL0` to EDITR.
   d. Write `MSR DBGDTR_EL0, X0` to EDITR. This dummy operation ensures EDSCR.TXfull == 1.
   e. Set EDSCR.MA to 1.
   f. Read DBGDTRTX_EL0 and discard the value. The PE returns the previous DTR value, loads the first word, and writes it to DTR. It increments X0 by 4.
2. Loop *n*-1 times. From the external debug interface:
   a. Read DBGDTRTX_EL0. The PE returns the previous DTRTX value, loads a new word, and writes it to DTRTX. It increments X0 by 4.
3. Epilogue. From the external debug interface:
   a. Clear EDSCR.MA to 0.
   b. Read DBGDTRTX_EL0 for the n^{th} value.
   c. Read EDSCR to check for underruns, overruns or Data Aborts during upload.

Appendix K10
Barrier Litmus Tests

This appendix gives examples of the use of the barrier instructions provided by the ARMv8 architecture. It contains the following sections:

- *Introduction* on page K10-5470.
- *Load-Acquire, Store-Release and barriers* on page K10-5473.
- *Load-Acquire Exclusive, Store-Release Exclusive and barriers* on page K10-5480.
- *Using a mailbox to send an interrupt* on page K10-5485.
- *Cache and TLB maintenance instructions and barriers* on page K10-5486.
- *ARMv7 compatible approaches for ordering, using DMB and DSB barriers* on page K10-5498.

Note

This information is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Non-Confidential - Beta

K10.1 Introduction

The exact rules for the insertion of barriers into code sequences is a very complicated subject, and this appendix describes many of the corner cases and behaviors that are possible in an implementation of the ARMv8 architecture.

This appendix is to help programmers, hardware design engineers, and validation engineers understand the need for the different kinds of barriers.

K10.1.1 Overview of memory consistency

Early generations of microprocessors were relatively simple processing engines that executed each instruction in program order. In such processors, the effective behavior was that each instruction was executed in its entirety before a subsequent instruction started to be executed. This behavior is sometimes referred to as the *Sequential Execution Model* (SEM), and in this Manual it is described as *Simple sequential execution* of the program.

In later processor generations, the needs to increase processor performance, both in terms of the frequency of operation and the number of instructions executed each cycle, mean that such a simple form of execution is abandoned. Many techniques, such as pipelining, write buffering, caching, speculation, and out-of-order execution, are introduced to provide improved performance.

For general purpose PEs, such as ARM, these microarchitectural innovations are largely hidden from the programmer by a number of microarchitectural techniques. These techniques ensure that, within an individual PE, the behavior of the PE largely remains the same as the SEM. There are some exceptions to this where explicit synchronization is required. In the ARM architecture, these are limited to cases such as:

- Synchronization of changes to the instruction stream.
- Synchronization of changes to System registers.

In both these cases, the `ISB` instruction provides the necessary synchronization.

While the effect of ordering is largely hidden from the programmer within a single PE, the microarchitectural innovations have a profound impact on the ordering of memory accesses. Write buffering, speculation, and cache coherency protocols, in particular, can all mean that the order in which memory accesses occur, as seen by an external observer, differs significantly from the order of accesses that would appear in the SEM. This is usually invisible in a uniprocessor environment, but the effect becomes much more significant when multiple PEs are trying to communicate with memory. In reality, these effects are often only significant at particular synchronization boundaries between the different threads of execution.

The problems that arise from memory ordering considerations are sometimes described as the problem of *memory consistency*. Processor architectures have adopted one or more *memory consistency models*, or *memory models*, that describe the permitted limits of the memory re-ordering that can be performed by an implementation of the architecture. The comparison and categorization of these has generated significant research and comment in academic circles, and ARM recommends the *Memory Consistency Models for Shared Memory-Multiprocessors* paper as an excellent detailed treatment of this subject.

This appendix does not reproduce such a work, but instead concentrates on some cases that demonstrate the features of the weakly-ordered memory model of the ARM architecture from ARMv6. In particular, the examples show how the use of the `DMB` and `DSB` memory barrier instructions can provide the necessary safeguards to limit memory ordering effects at the required synchronization points.

K10.1.2 Barrier operation definitions

The following reference, or provide, definitions of terms used in this appendix:

DMB See *Data Memory Barrier (DMB)* on page B2-87.

DSB See *Data Synchronization Barrier (DSB)* on page B2-88.

ISB See *Instruction Synchronization Barrier (ISB)* on page B2-87.

Observer, Completion

See *Observability and completion* on page B2-83.

Program order

The order of instructions as they appear in an assembly language program. This appendix does not attempt to describe or define the legal transformations from a program written in a higher level programming language, such as C or C++, into the machine language that can then be disassembled to give an equivalent assembly language program. Such transformations are a function of the semantics of the higher level language and the capabilities and options on the compiler.

K10.1.3 Conventions

Many of the examples are written in a stylized extension to ARM assembler, to avoid confusing the examples with unnecessary code sequences.

AArch32

The construct `WAIT([Rx]==1)` describes the following sequence:

```
loop
    LDR R12, [Rx]
    CMP R12, #1
    BNE loop
```

Also, the construct `WAIT_ACQ([Rx]==1)` describes the following sequence:

```
   loop
    LDA R12, [Rx]       ; load acquire ensures it is ordered before subsequent loads/stores
    CMP R12, #1
    BNE loop
```

R12 is chosen as an arbitrary temporary register that is not in use. It is named to permit the generation of a false dependency to ensure ordering.

AArch64

The construct `WAIT([Xx]==1)` describes the following sequence:

```
loop
    LDR W12, [Xx]
    CMP W12, #1
    B.NE loop
```

Also, the construct `WAIT_ACQ([Xx]==1)` and describes the following sequence:

```
   loop
    LDAR W12, [Xx]       ; load acquire ensures it is ordered before subsequent loads/stores
    CMP W12, #1
    B.NE loop
```

For each example, a code sequence is preceded by an identifier of the observer running it:

- P0, P1…P*x* refer to caching coherent PEs that implement the ARMv8 architecture, and are in the same shareability domain.
- E0, E1…E*x* refer to non-caching observers, that do not participate in the coherency protocol, but execute ARM instructions and have a weakly-ordered memory model. This does not preclude these observers being different objects, such as DMA engines or other system masters.

These observers are unsynchronized other than as required by the documented code sequence.

Note

Throughout this appendix, *ARM instruction* and *instruction* refer to instructions from the A64, A32, or T32 instruction set, provided by ARMv8 implementations.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Results are expressed in terms of `<agent>:<register>`, such as `P0:R5`. The results can be described as:

Permissible This does not imply that the results expressed are required or are the only possible results. In most cases they are results that would not be possible under a sequentially consistent running of the code sequences on the agents involved. In general terms, this means that these results might be unexpected to anyone unfamiliar with memory consistency issues.

Not permissible Results that the architecture expressly forbids.

Required Results that the architecture expressly requires.

The examples omit the required shareability domain arguments of `DMB` and `DSB` instructions. The arguments are assumed to be selected appropriately for the shareability domains of the observers.

In AArch32 state, where the barrier function in the litmus test can be achieved by a `DMB ST`, that is a barrier to stores only, this is shown by the use of `DMB [ST]`. This indicates that the `ST` qualifier can be omitted without affecting the result of the test. In some implementations `DMB ST` is faster than `DMB`.

For AArch64 code, the shareability domain of the `DMB` or `DSB` must be included. This is shown in this manual using the notation `DMB <domain>` and `DSB <domain>` respectively.

Except where otherwise stated, other conventions are:

- All memory initializes to 0.
- R0 and W0 contain the value 1.
- R1 - R4 and W1 - W4 contain arbitrary independent addresses that initialize to the same value on all PEs. The addresses held in these registers are shareable and:
  - The addresses held in R1 and R2 are in Write-Back Cacheable Normal memory.
  - The address held in R3 is in Write-Through Cacheable Normal memory.
  - The address held in R4 is in Non-cacheable Normal memory.
- R5 - R8 and W5 - W8 contain:
  - When used with an `STR` instruction, `0x55`, `0x66`, `0x77`, and `0x88` respectively.
  - When used with an `LDR` instruction, the value 0.
- R11 and W11 contain a new instruction or new translation table entry, as appropriate, and R10 contains the virtual address and the ASID, for use in this change of translation table entry.
- Memory locations are Normal memory locations unless otherwise stated.

The examples use mnemonics for the cache maintenance and TLB maintenance instructions. The following tables describe the mnemonics:

- *Cache maintenance instructions, functional group* on page G4-4055.
- *TLB maintenance instructions, functional group* on page G4-4057.

K10.2 Load-Acquire, Store-Release and barriers

The Load-Acquire and Store-Release instructions are described in *Load-Acquire, Store-Release* on page B2-89.

The following sections show that most of the examples in sections *Simple ordering and barrier cases* on page K10-5498 and *Load-Exclusive, Store-Exclusive and barriers* on page K10-5504 can be achieved using the Load-Acquire and Store-Release instructions without the need for additional barriers.

K10.2.1 Message passing

The following sections describe:

- *Resolving weakly-ordered message passing by using Acquire and Release*.
- *Resolving message passing by the use of Store-Release and address dependency* on page K10-5474.

Resolving weakly-ordered message passing by using Acquire and Release

The message passing problem described in *Weakly-ordered message passing problem* on page K10-5498 can be solved by the use of Load-Acquire and Store-Release instructions when accessing the communications flag:

AArch32

P1

```
STR R5, [R1]          ; sets new data
STL R0, [R2]          ; sends flag indicating data ready, which is ordered after the STR
```

P2

```
WAIT_ACQ([R2]==1)     ; waits on flag
LDR R5, [R1]
```

AArch64

P1

```
STR W5, [X1]          ; sets new data
STLR W0, [X2]         ; sends flag indicating data ready, which is ordered after the STR
```

P2

```
WAIT_ACQ([X2]==1)     ; waits on flag
LDR W5, [X1]
```

This ensures the observed order of both the reads and the writes allows transfer of data such that the result P2:R5==0x55 is guaranteed.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

AArch32

P3

```
WAIT_ACQ([R2]==1)     ; waits on flag
LDR R5, [R1]
```

AArch64

P3

```
WAIT_ACQ([X2]==1)     ; waits on flag
LDR W5, [X1]
```

Resolving message passing by the use of Store-Release and address dependency

The lack of ordering of stores discussed in *Message passing with multiple observers* on page K10-5500 can be resolved by the use of Store-Release for the store of the valid flag by P1, even when the observers are using an address dependency:

AArch32

P1

```
STR R5, [R1]          ; sets new data
STL R0, [R2]          ; sends flag indicating data ready using a Store-Release
```

P2

```
WAIT([R2]==1)
AND R12, R12, #0      ; R12 is the destination of LDR in the WAIT macro
LDR R5, [R1, R12]     ; the load has an address dependency on R12
                      : and so is ordered after the flag has been seen
```

AArch64

P1

```
STR W5, [X1]          ; sets new data
STLR W0, [X2]         ; sends flag indicating data ready using a Store-Release
```

P2

```
WAIT([X2]==1)
AND W12, W12, WZR     ; W12 is the destination of LDR in the WAIT macro
LDR W5, [X1, X12]     ; the load has an address dependency on W12
                      : and so is ordered after the flag has been seen
```

This ensures the observed order of the writes allows transfer of data such that P2:R5 and P3:R5 contain the same value of `0x55`.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

AArch32

P3

```
WAIT([R2]==1)
AND R12, R12, #0      ; R12 is the destination of LDR in the WAIT macro
LDR R5, [R1, R12]     ; the load has an address dependency on R12
                      : and so is ordered after the flag has been seen
```

AArch64

P3

```
WAIT([X2]==1)
AND W12, W12, WZR     ; R12 is the destination of LDR in the WAIT macro
LDR W5, [X1, X12]     ; the load has an address dependency on W12
                      : and so is ordered after the flag has been seen
```

Non-Confidential - Beta

K10.2.2 Address dependency with object construction

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object. A Store-Release can be used to ensure the order of the update of the base address:

AArch32

P1

```
STR R5, [R1, #offset] ; sets new data in a field
STL R1, [R2]          ; updates base address
```

P2

```
LDR R1, [R2]          ; reads base address
CMP R1, #0            ; checks if it is valid
BEQ null_trap
LDR R5, [R1, #offset] ; uses base address to read field
```

AArch64

P1

```
STR W5, [X1, #offset] ; sets new data in a field
STLR X1, [X2]         ; updates base address
```

P2

```
LDR X1, [X2]          ; reads base address
CMP X1, #0            ; check if it is valid
B.EQ null_trap
LDR W5, [X1, #offset] ; uses base address to read field
```

It is required that P2:R5==0x55 if the null_trap is not taken. This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not need a barrier to ensure this behavior.

The read of the base address in P2 could be a Load-Acquire, but it is not necessary in this case.

K10.2.3 Causal consistency issues with multiple observers

The cause consistent problem discussed in *Causal consistency issues with multiple observers* on page K10-5501 can be addressed by the use of a Store-Release, as this requires that the store is multicopy atomic in the case of a Load-Acquire. In addition, a Store-Release has an effect on the observation order of any stores observed by the observer executing the Store-Release.

The following sequences guarantee causal consistency:

- *Using multi-copy atomicity of the Store-Release when observed by Load-Acquire*.
- *Using ordering property of Store-Release on stores observed by the PE* on page K10-5476.

Using multi-copy atomicity of the Store-Release when observed by Load-Acquire

AArch32

P1

```
STL R0, [R2]          ; sets new data
                      ; this is made multi-copy atomic
```

P2

```
WAIT_ACQ([R2]==1)     ; waits to see new data from P1
STR R0, [R3]          ; sends flag
                      ; must be after the new data has been by P2,
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

```
                        ; as stores must not be speculative
                        ; this does not need to be a Store-Release,
                        ; though it could be a Store-Release
```

P3

```
    WAIT([R3]==1)       ; waits for P2 flag
                        ; this does not need to be a WAIT_ACQ, although
                        ; it could be a WAIT_ACQ (at which point the dependency is not needed)
    AND R12, R12, #0    ; dependency to ensure order (only needed for a WAIT, not WAIT_ACQ)
    ADD R12, R2, R12    ; creating a dependency
    LDA R0, [R12]       ; reads P1 data using a Load-Acquire
```

AArch64

P1

```
    STLR W0, [X2]       ; sets new data
                        ; this is made multi-copy atomic
```

P2

```
    WAIT_ACQ([X2]==1)   ; waits to see new data from P1
    STR W0, [X3]        ; sends flag
                        ; must be after the new data has been by P2 as stores
                        ; must not be speculative.
                        ; this does not need to be a Store-Release,
                        ; though it could be a Store-Release
```

P3

```
    WAIT([X3]==1)       ; waits for P2 flag
                        ; this does not need to be a WAIT_ACQ, though
                        ; it could be a WAIT_ACQ (at which point the dependency is not needed
    AND W12, W12, WZR   ; dependency to ensure order (only needed for a WAIT, not WAIT_ACQ)
    ADD X12, X2, X12    ; creating a dependency
    LDAR W0, [X12]      ; reads P1 data using a Load-Acquire
```

In this case, P3:R0 == 0 is not permissible. P3 is guaranteed to see the store from P1 if P2 has seen the store from P1 using a Load-Acquire.

Using ordering property of Store-Release on stores observed by the PE

AArch32

P1

```
    STR R0, [R2]        ; sets new data
                        ; this does not have to be a Store-Release, though it
                        ; could be a Store-release
```

P2

```
    WAIT ([R2]==1)      ; waits to see new data from P1
                        ; this does not need to be a WAIT_ACQ, though it could be a WAIT_ACQ
    STL R0, [R3]        ; sends flag
                        ; this must be after the new data has been seen by P2
                        : as stores must not be speculative,
                        ; as a Store-Release, this orders the P1 store
```

P3

```
    WAIT([R3]==1)       ; waits for P2 flag
                        ; this does not need to be a WAIT_ACQ, although it could be a WAIT_ACQ
                        ; (at which point the dependency is not needed)
    AND R12, R12, #0    ; dependency to ensure order (only needed for a WAIT, not WAIT_ACQ)
    LDR R0, [R2, R12]   ; reads P1 data
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

AArch64

P1

```
    STR W0, [X2]          ; sets new data
                          ; this does not have to be a Store-Release, though it
                          ; could be a Store-Release
```

P2

```
    WAIT ([X2]==1)        ; waits to see new data from P1
                          ; this does not need to be a WAIT_ACQ, though it could be a WAIT_ACQ
    STLR W0, [X3]         ; sends flag
                          ; this must be after the new data has been seen by P2
                          : as stores must not be speculative,
                          ; as a Store-Release, this orders the P1 store
```

P3

```
    WAIT([X3]==1)         ; waits for P2 flag
                          ; this does not need to be a WAIT_ACQ, though it could be a WAIT_ACQ
                          ; at which point the dependency is not needed
    AND W12, W12, WZR     ; dependency to ensure order
                          ; only needed for a WAIT, not WAIT_ACQ
    LDR W0, [X2, X12]     ; reads P1 data
```

In this case, P3:R0 == 0 is not permissible. P3 is guaranteed to see the store from P1 if P2 has seen the store from P1 before it does the Store-Release that is then seen by P3.

Note

The use of dependency by P3 could be replaced by a Load-Acquire.

K10.2.4 Multiple observers of writes to multiple locations

The ARM weakly consistent memory model means that different observers can observe writes to different locations in different orders as was shown in *Multiple observers of writes to multiple locations* on page K10-5501, but the use of Load-Acquire and Store-Release can resolve this. In this case, the loads by P3 and P4 must be Load-Acquire in order to ensure the perceived multi-copy atomicity of the stores:

AArch32

P1

```
    STL R0, [R1]          ; sets new data
```

P2

```
    STL R0, [R2]          ; sets new data
```

P3

```
    LDA R10, [R2]         ; reads P2 data before P1
    LDA R9, [R1]          ;
    BIC R9, R10, R9       ; R9  <- R10 & ~R9
                          ; R9 contains 1 if read from [R2] is observed to be 1 and
                          ; read from [R1] is observed to be 0
```

P4

```
    LDA R9, [R1]
    LDA R10, [R2]
    BIC  R9, R9, R10      ; R9 <- R9 & ~R10
                          ; R9 contains 1 if read from [R2] is observed to be 0 and
                          ; read from [R1] is observed to be 1
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

AArch64

P1

```
    STLR W0, [X1]         ; sets new data
```

P2

```
    STLR W0, [X2]         ; sets new data
```

P3

```
    LDAR W10, [X2]        ; reads P2 data before P1
    LDAR W9, [X1]         ;
    BIC W9, W10, W9       ; W9  <- W10 & ~W9
                          ; W9 contains 1 if read from [X2] is observed to be 1 and
                          ; read from [X1] is observed to be 0
```

P4

```
    LDAR W9, [X1]
    LDAR W10, [X2]
    BIC  W9, W9, W10      ; W9 <- W9 & ~W10
                          ; W9 contains 1 if read from [X2] is observed to be 0 and
                          ; read from [X1] is observed to be 1
```

In this case, the result P3:R9==1 and P4:R9==1 is not permissible, as the stores from P1 and P2 are multi-copy atomic when read by Load-Acquire.

Therefore, if P3 gets R10==1, then we know that the P3 load of R9 can only be observed after we know that P4 has also observed the P2 store to [R2]. Similarly, if the P4 load of R9 returns 1, and the P3 load of R9 returns 0, then the P3 load must have occurred before the P4 load.

Therefore, if the P3 load of R10 returns 1 and the P3 load of R9 returns 0, then we know that if the P4 load of R9 returns 1, it must have happened after P4 has observed the P2 store to [R2], so the P4 load of R10 must return 1.

This shows that, of the 4 possible values for {P3:R9, P4:R9}, the use of these instructions makes the result {1,1} impossible.

Non-Confidential - Beta

K10.2.5 WFE and WFI and barriers

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. An explicit `DSB` barrier instruction is required if it is necessary to ensure memory accesses made before the `WFI` or `WFE` are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanism that would guarantee the required visibility are the `DMB` described in *Posting a store before polling for acknowledgement* on page K10-5503, or a dependency on a load.

The following example requires the `DSB` to ensure that the store is visible:

AArch32

P1

```
    STR R0, [R2]
    DSB
Loop
    WFI
    B Loop
```

AArch64

P1

```
    STR W0, [X2]
    DSB <domain>
Loop
    WFI
    B Loop
```

This requirement is unchanged in ARMv8 by the presence of Load-Acquire or Store-Release.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

K10.3 Load-Acquire Exclusive, Store-Release Exclusive and barriers

The ARMv8 architecture adds the acquire and release semantics to Load-Exclusive and Store-Exclusive instructions, which allows them to gain ordering acquire and/or release semantics.

The Load-Exclusive instruction can be specified to have acquire semantics, and the Store-Exclusive instruction can be specified to have release semantics. These can be arbitrarily combined to allow the atomic update created by a successful Load-Exclusive and Store-Exclusive pair to have any of:

- No Ordering semantics (using `LDREX` and `STREX`).
- Acquire only semantics (using `LDAEX` and `STREX`).
- Release only semantics (using `LDREX` and `STLEX`).
- Sequentially consistent semantics (using `LDAEX` and `STLEX`).

In addition, the ARMv8 specification requires that the clearing of a global monitor will generate an event for the PE associated with the global monitor, which can simplify the use of `WFE`, by removing the need for a `DSB` barrier and `SEV` instruction.

K10.3.1 Acquiring a lock

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.

For a critical region, the requirement on taking a lock is usually for acquire semantics, while the clearing of a lock requires release semantics:

AArch32

Px

```
    PLDW[R1]              ; preload into cache in unique state
Loop
    LDAEX R5, [R1]        ; read lock with acquire
    CMP R5, #0            ; check if 0
    STREXEQ R5, R0, [R1]  ; attempt to store new value
    CMPEQ R5, #0          ; test if store suceeded
    BNE Loop              ; retry if not

    ; loads and stores in the critical region can now be performed
```

AArch64

Px

```
    PRFM PSTL1KEEP, [X1]  ; preload into cache in unique state
Loop
    LDAXR W5, [X1]        ; read lock with acquire
    CBNZ W5, Loop         ; check if 0
    STXR W5, W0, [X1]     ; attempt to store new value
    CBNZ W5, Loop         ; test if store succeeded and retry if not

    ; loads and stores in the critical region can now be performed
```

The acquire associated with the load is sufficient to ensure the required ordering in a lock situation. The Store-Exclusive will fail (and so be retried) if there is a store to the location being monitored between the Load-Exclusive and the Store-Exclusive.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

K10.3.2 Releasing a lock

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, the lock release needs release semantics:

AArch32

Px

```
    ; loads and stores in the critical region
    MOV R0, #0
    STL R0, [R1]          ; clear the lock with release semantics
```

AArch64

Px

```
    ; loads and stores in the critical region
    STLR WZR, [X1]        ; clear the lock with release semantics
```

K10.3.3 Ticket locks

When a lock is free, in order to avoid a rush to get the lock by many PEs, the use of ticket locks is common in more advanced systems. When the use is requested, the ticket locks determine the order of the users of the critical sections, in order to avoid starvation that can occur with a simple contention based spin lock.

A ticket lock allocates each thread a ticket number when it first requests the lock, and then compares that number with the current number for the lock. If they are the same, then the critical section can be entered. Otherwise the thread waits until the current number is equal to the ticket number for that thread.

The reading of the current number of the lock needs acquire semantics for the lock to be acquired.

Note

The code in this section is little-endian code, as it views the combined current and next values as a single combined quantity. The addresses of the current and next ticket values need to be adjusted for a big-endian system.

This is shown in the implementation below:

AArch32

Px

```
    ; R1 holds two 16 bit quantities
    ; the lower halfword holds the current ticket number
    ; the higher halfword holds the next ticket number

    PLDW[R1]              ; preload into cache in unique state
Loop1
    LDAEX R5, [R1]        ; read current and next
    ADD R5, R5, #0x10000  ; increment the next number
    STREX R6, R5, [R1]    ; and update the value
    CMP R6, #0            ; did the exclusive pass
    BNE Loop1             ; retry if not
    CMP R5, R5, ROR #16   ; is the current ticket ours
    BEQ block_start
Loop2
    LDAH R6, [R1]         ; read current value
    CMP R6, R5, LSR #16   ; compare it with our allocated ticket
    BNE Loop2             ; retry (spin) if it is not the same
block_start
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

AArch64

Px

```
    ; X1 holds 2 16 bit quantities
    ; the lower halfword holds the current ticket number
    ; the higher halfword holds the next ticket number

    PRFM PSTL1KEEP, [X1]  ; preload into cache in unique state
Loop1
    LDAXR W5, [X1]        ; read current and next
    ADD W5, W5, #0x10000  ; increment the next number
    STXR W6, W5, [X1]     ; and update the value
    CBNZ W6, Loop1        ; did the exclusive pass - retry if not

    AND W6, W5, #0xFFFF
    CMP W6, W5, LSR #16   ; is the current ticket ours
    B.EQ block_start
Loop2
    LDARH W6, [X1]        ; read current value
    CMP W6, W5, LSR #16   ; compare it with the our allocated ticket
    B.NE Loop2            ; retry (spin) if it isn't the same
block_start
```

Releasing the ticket lock simply involves incrementing the current ticket number, that is still assumed to be in R3, and doing a Store-Release:

AArch32

```
    ADD R6, R6, #1
    STLH R6, [R1]
```

AArch64

```
    ADD W6, W6, #1
    STLRH W6, [X1]
```

K10.3.4 Use of Wait For Event (WFE) and Send Event (SEV) with locks

The ARMv8 architecture can use the Wait For Event mechanism to minimise the energy cost of polling variables by putting the PE into a low power state, suspending execution, until an asynchronous exception or an explicit event is seen by that PE. In ARMv8, the event can be generated as a result of clearing the global monitor, so removing the need for a `DSB` barrier or an explicit send event message.

This can be used with simple locks or with ticket locks.

Simple lock

The following is an example of lock acquire code using `WFE`:

AArch32

Px

```
    PLDW[R1]              ; preload into cache in unique state
Loop
    LDAEX R5, [R1]        ; read lock with acquire
    CMP R5, #0            ; check if 0
    WFENE                 ; sleep if the lock is held
    STREXEQ R5, R0, [R1]  ; attempt to store new value
    CMPEQ R5, #0          ; test if store succeeded
    BNE Loop              ; retry if not
```

AArch64

Px

```
    SEVL                ; invalidates the WFE on the first loop iteration
    PRFM PSTL1KEEP, [X1]  ; allocate into cache in unique state
Loop
    WFE
    LDAXR W5, [X1]        ; read lock with acquire
    CBNZ W5, Loop         ; check if 0
    STXR W5, W0, [X1]     ; attempt to store new value
    CBNZ W5, Loop         ; test if store succeeded and retry if not

    ; loads and stores in the critical region can now be performed
```

And the following is an example of lock release code:

AArch32

Px

```
    ; loads and stores in the critical region
    MOV R0, #0
    STL R0, [R1]          ; clear the lock
```

AArch64

Px

```
    ; loads and stores in the critical region
    STLR WZR, [X1]        ; clear the lock
```

Ticket lock

In the Ticket lock case, the Load-Exclusive instruction can be used to move the monitor into the exclusive state for the express purpose of creating an event when the monitor changes state:

AArch32

Px

```
    ; R1 holds 2 16 bit quantities
    ; the lower halfword holds the current ticket number
    ; the higher halfword holds the next ticket number

    PLDW[R1]              ; preload into cache in unique state
Loop1
    LDAEX R5, [R1]        ; read current and next
    ADD R5, R5, #0x10000  ; increment the next number
    STREX R6, R5, [R1]    ; and update the value
    CMP R6, #0            ; did the exclusive pass
    BNE Loop              ; retry if not
    CMP R5, R5, ROR #16   ; is the current ticket ours
    BEQ block_start
    SEVL
Loop2
    WFE                   ; wait if there has not been a change to the count since last
                          ; read
    LDAEXH R6, [R1]       ; check the current count
    CMP R6, R5, LSR #16   ; check if it is equal
    BNE Loop2
block_start
```

K10.4 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a `DSB` instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

AArch32

P1

```
STR R5, [R1]          ; message stored to shared memory location
DSB ST
STR R0, [R4]          ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR R5, [R1]
```

AArch64

P1

```
STR W5, [X1]          ; message stored to shared memory location
DSB ST
STR W0, [X4]          ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR W5, [X1]
```

K10.5 Cache and TLB maintenance instructions and barriers

The following sections describe the use of barriers with cache and TLB maintenance instructions:

- *Data cache maintenance instructions*.
- *Instruction cache maintenance instructions* on page K10-5490.
- *TLB maintenance instructions and barriers* on page K10-5493.

K10.5.1 Data cache maintenance instructions

The following sections describe the use of barriers with data cache maintenance instructions:

- *Message passing to non-caching observers*.
- *Multiprocessing message passing to non-caching observers* on page K10-5487.
- *Invalidating DMA buffers, non-functional example* on page K10-5488.
- *Invalidating DMA buffers, functional example with single PE* on page K10-5488.
- *Invalidating DMA buffers, functional example with multiple coherent PEs* on page K10-5489.

Message passing to non-caching observers

The ARMv8 architecture requires the use of `DMB` instructions to ensure the ordering of data cache maintenance instructions and their effects. The Load-Acquire and Store-Release instructions have no effect on cache maintenance instruction. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

AArch32

P1

```
STR R5, [R1]          ; updates data (assumed to be in P1 cache)
DCCMVAC R1            ; cleans cache to point of coherency
DMB                   ; ensures effects of the clean will be observed before the
                      ; flag is set
STR R0, [R4]          ; sends flag to external agent (Non-cacheable location)
```

E1

```
WAIT_ACQ ([R4] == 1)  ; waits for the flag (with order)
LDR R5, [R1]          ; reads the data
```

AArch64

P1

```
STR W5, [X1]          ; updates data (assumed to be in P1 cache)
DC CVAC, X1           ; cleans cache to point of coherency
DMB ISH               ; ensures effects of the clean will be observed before the
                      ; flag is set
STR W0, [X4]          ; sends flag to external agent (Non-cacheable location)
```

E1

```
WAIT_ACQ ([X4] == 1)  ; waits for the flag (with order)
LDR W5, [X1]          ; reads the data
```

In this example, it is required that E1:R5==`0x55`.

Non-Confidential - Beta

Multiprocessing message passing to non-caching observers

The broadcast nature of the cache maintenance instructions combined with properties of barriers, means that the message passing principle for non-caching observers is:

AArch32

P1

```
    STR R5, [R1]          ; updates data (assumed to be in P1 cache)
    STL R0, [R2]          ; sends a flag for P2 (ordered by the store release)
```

P2

```
    WAIT ([R2] == 1)      ; waits for P1 flag
    DMB                   ; ensures cache clean is observed after P1 flag is observed
    DCCMVAC R1            ; cleans cache to point of coherency - will clean P1 cache
    DMB                   ; ensures effects of the clean will be observed before the
                          ; flag to E1 is set
    STR R0, [R4]          ; sends flag to E1
```

E1

```
    WAIT_ACQ ([R4] == 1)  ; waits for P2 flag (ordered)
    LDR R5, [R1]          ; reads data
```

AArch64

P1

```
    STR W5, [X1]          ; updates data (assumed to be in P1 cache)
    STLR W0, [X2]         ; sends a flag for P2 (ordered)
```

P2

```
    WAIT ([X2] == 1)      ; waits sfor P1 flag
    DMB SY                ; ensure cache clean is observed after P1 flag is observed
    DC CVAC, X1           ; cleans cache to point of coherency, will clean P1 cache
    DMB SY                ; ensures effects of the clean will be observed before the
                          ; flag to E1 is set
    STR W0, [X4]          ; sends flag to E1
```

E1

```
    WAIT_ACQ ([X4] == 1)  ; waits for P2 flag
    LDR W5, [X1]          ; reads data
```

In this example, it is required that E1:R5==0x55. The clean operation executed by P2 affects the data location in the P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

Note

The cache maintenance instructions are not ordered by the Load-Acquire and Store-Release instructions.

Invalidating DMA buffers, non-functional example

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable memory region must take account of the architectural requirement that regions marked as Cacheable can be allocated into a cache at any time, for example as a result of speculation. The following example shows this possibility:

AArch32

P1

```
    DCIMVAC R1            ; ensures cache is not dirty. A clean operation could be used
                          ; but as the DMA will subsequently overwrite this region an
                          ; invalidate operation is sufficient and usually more efficient
    DMB                   ; ensures cache invalidation is observed before the next store
                          ; is observed
    STR R0, [R3]          ; sends flag to external agent
    WAIT_ACQ ([R4]==1)    ; waits for a different flag from an external agent
    LDR R5, [R1]
```

E1

```
    WAIT ([R3] == 1)      ; waits for flag
    STR R5, [R1]          ; stores new data
    STL R0, [R4]          ; sends a flag
```

AArch64

P1

```
    DC IVAC, X1           ; ensure cache is not dirty. A clean operation could be used
                          ; but as the DMA will subsequently overwrite this region an
                          ; invalidate operation is sufficient and usually more efficient
    DMB SY                ; ensures cache invalidation is observed before the next store
                          ; is observed
    STR W0, [X3]          ; sends flag to external agent
    WAIT_ACQ ([X4]==1)    ; waits for a different flag from an external agent
    LDR W5, [X1]
```

E1

```
    WAIT ([X3] == 1)      ; waits for flag
    STR W5, [X1]          ; stores new data
    STLR W0, [X4]         ; sends a flag
```

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.

Invalidating DMA buffers, functional example with single PE

AArch32

P1

```
    DCIMVAC R1            ; ensures cache is not dirty. A clean operation could be used
                          ; but as the DMA will subsequently overwrite this region an
                          ; invalidate operation is sufficient and usually more efficient
    DMB                   ; ensures cache invalidation is observed before the next store
                          ; is observed
    STR R0, [R3]          ; sends flag to external agent
    WAIT ([R4]==1)        ; waits for a different flag from an external agent
    DMB                   ; ensures that cache invalidate is observed after the flag
                          ; from external agent is observed
    DCIMVAC R1            ; ensures cache discards stale copies before use
    LDR R5, [R1]
```

E1

```
    WAIT ([R3] == 1)      ; waits for flag
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

```
    STR R5, [R1]          ; stores new data
    STL R0, [R4]          ; sends a flag
```

AArch64

P1

```
    DC IVAC, X1           ; ensures cache is not dirty. A clean operation could be used
                          ; but as the DMA will subsequently overwrite this region an
                          ; invalidate operation is sufficient and usually more efficient
    DMB SY                ; ensures cache invalidation is observed before the next store
                          ; is observed
    STR W0, [X3]          ; sends flag to external agent
    WAIT ([X4]==1)        ; waits for a different flag from an external agent
    DMB SY                ; ensures that cache invalidate is observed after the flag
                          ; from external agent is observed
    DC IVAC, X1           ; ensures cache discards stale copies before use
    LDR W5, [X1]
```

E1

```
    WAIT ([X3] == 1)      ; waits for flag
    STR W5, [X1]          ; stores new data
    STLR W0, [X4]         ; sends a flag
```

In this example, the result P1:R5 == `0x55` is required. Including a cache invalidation after the store by E1 to [R1] is observed ensures that the line is fetched from external memory after it has been updated.

Invalidating DMA buffers, functional example with multiple coherent PEs

The broadcasting of cache maintenance instructions, and the use of `DMB` instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

AArch32

P0

```
    (Use data from [R1], potentially using [R1] as scratch space)
    STL R0, [R2]          ; signals release of [R1]
    WAIT_ACQ ([R2] == 0)  ; waits for new value from DMA
    LDR R5, [R1]
```

P1

```
    WAIT ([R2] == 1)      ; waits for release of [R1] by P0
    DCIMVAC R1            ; ensures caches are not dirty, an invalidate is sufficient
    DMB
    STR R0, [R3]          ; requests new data for [R1]
    WAIT ([R4] == 1)      ; waits for new data
    DMB
    DCIMVAC R1            ; ensures caches discard stale copies before use
    DMB
    MOV R0, #0
    STR R0, [R2]          ; signals availability of new [R1]
```

E1

```
    WAIT ([R3] == 1)      ; waits for new data request
    STR R5, [R1]          ; sends new [R1]
    DMB [ST]
    STR R0, [R4]          ; indicates that new data is available to P1
```

AArch64

P0

```
    (Use data from [X1], potentially using [X1] as scratch space)
    STLR W0, [X2]         ; signals release of [X1]
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

```
    WAIT_ACQ ([X2] == 0)  ; waits for new value from DMA
    LDR W5, [X1]
```

P1

```
    WAIT ([X2] == 1)      ; waits for release of [R1] by P0
    DC IVAC, X1           ; ensures caches are not dirty, an invalidate is sufficient
    DMB SY
    STR W0, [X3]          ; requests new data for [R1]
    WAIT ([X4] == 1)      ; waits for new data
    DMB SY
    DCIMVAC X1            ; ensures caches discard stale copies before use
    DMB SY
    STR WZR, [X2]         ; signals availability of new [R1]
```

E1

```
    WAIT ([X3] == 1)      ; waits for new data request
    STR W5, [X1]          ; sends new [R1]
    STR W0, [X4]          ; indicates new data is available to P1
```

In this example, the result P0:R5 == `0x55` is required. The `DMB` issued by P1 after the first data cache invalidation ensures that effect of the cache invalidation on P0 is seen by E1 before the store by E1 to [R1]. The `DMB` issued by P1 after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in [R2].

K10.5.2 Instruction cache maintenance instructions

The following sections describe the use of barriers with instruction cache maintenance instructions:

- *Ensuring the visibility of updates to instructions for a uniprocessor*.
- *Ensuring the visibility of updates to instructions for a multiprocessor* on page K10-5491.

Ensuring the visibility of updates to instructions for a uniprocessor

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a `DSB` instruction.

Also, instruction cache maintenance instructions are only guaranteed to complete after the execution of a `DSB`, and an `ISB` is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

AArch32

P1

```
    STR R11, [R1]         ; R11 contains a new instruction to be stored in program memory
    DCCMVAU R1            ; clean to PoU makes the new instruction visible to the instruction cache
    DSB
    ICIMVAU R1            ; ensures instruction cache/branch predictor discards stale data
    BPIMVA R1
    DSB                   ; ensures completion of the invalidation
    ISB                   ; ensures instruction fetch path sees new instruction cache state
    BX R1
```

In AArch64, the branch predictor maintenance is not required.

AArch64

P1

```
    STR W11, [X1]         ; W11 contains a new instruction to be stored in program memory
    DC CVAU, X1           ; clean to PoU makes the new instruction visible to instruction cache
    DSB ISH
    IC IVAU, X1           ; ensures instruction cache/branch predictor discards stale data
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

```
DSB ISH              ; ensures completion of the invalidation
ISB                  ; ensures instruction fetch path sees new instruction cache state
BR X1
```

Note

Where the changes to the instructions span multiple cache lines, then the data cache and instruction cache maintenance instructions can be duplicated to cover each of the lines to be cleaned and to be invalidated.

Ensuring the visibility of updates to instructions for a multiprocessor

The ARMv8 architecture requires a PE that executes an instruction cache maintenance instruction to execute a `DSB` instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

An `ISB` is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own `ISB` synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:

AArch32

P1

```
STR R11, [R1]        ; R11 contains a new instruction to be stored in program memory
DCCMVAU R1           ; clean to PoU makes the new instruction visible to the instruction cache
DSB                  ; ensures completion of the clean on all PEs
ICIMVAU R1           ; ensures instruction cache discards stale data
BPIMVA R             ; ensures branch predictor discards stale data
DSB                  ; ensures completion of the instruction cache and branch predictor
                     ; invalidation on all PEs
STR R0, [R2]         ; sets flag to signal completion
ISB                  ; synchronizes context on this PE
BX R1                ; branches to new code
```

P2-P*x*

```
WAIT ([R2] == 1)     ; waits for flag signalling completion
ISB                  ; synchronizes context on this PE
BX R1                ; branches to new code
```

AArch64

P1

```
STR X11, [X1]        ; X11 contains a new instruction to be stored in program memory
DC CVAU, X1          ; clean to PoU makes the new instruction visible to the instruction cache
DSB ISH              ; ensures completion of the clean on all PEs
IC IVAU, X1          ; ensures instruction cache/branch predictor discards stale data
DSB ISH              ; ensures completion of the instruction cache/branch predictor
                     ; invalidation on all PEs
STR W0, [X2]         ; sets flag to signal completion
ISB                  ; synchronizes context on this PE
BR R1                ; branches to new code
```

P2-P*x*

```
WAIT ([X2] == 1)     ; waits for flag signalling completion
ISB                  ; synchronizes context on this PE
BR X1                ; branches to new code
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Nonfunctional approach

The following sequence does not have the same effect, because a `DSB` is not required to complete the instruction cache maintenance instructions that other PEs issue:

AArch32

P1

```
STR R11, [R1]          ; R11 contains a new instruction to be stored in program memory
DCCMVAU R1             ; clean to PoU makes the new instruction visible to the instruction cache
DSB                    ; ensures completion of the clean on all PEs
ICIMVAU R1             ; ensures instruction cache discards stale data
BPIMVA R1              : ensures branch predictor discards stale data
DMB                    ; ensures ordering of the store after the invalidation
                       ; DOES NOT guarantee completion of instruction cache/branch

K10.5.3 TLB maintenance instructions and barriers

The following sections describe the use of barriers with TLB maintenance instructions:

- *Ensuring the visibility of updates to translation tables for a uniprocessor*.
- *Ensuring the visibility of updates to translation tables for a multiprocessor* on page K10-5494.
- *Paging memory in and out* on page K10-5494.
- *Break-before-make updates to translation table entries* on page K10-5495.

Ensuring the visibility of updates to translation tables for a uniprocessor

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a `DSB` instruction.

The ARMv8 architecture requires that translation table walks look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a `DSB` and an `ISB`. Therefore, the code for updating a translation table entry is:

AArch32

P1

```
STR R11, [R1]         ; updates the translation table entry
DSB                   ; ensures visibility of the update to translation table walks
TLBIMVA R10
BPIALL
DSB                   ; ensures completion of the BP and TLB invalidation
ISB                   ; synchronises context on this PE
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using
; the old mapping have been completed
```

AArch64

P1

```
STR X11, [X1]         ; updates the translation table entry
DSB ISH               ; ensures visibility of the update to translation table walks
TLBI VAE1, X10        ; assumes we are in the EL1
DSB ISH               ; ensures completion of the TLB invalidation
ISB                   ; synchronise context on this PE
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using
; the old mapping have been completed
```

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.

Non-Confidential - Beta

Ensuring the visibility of updates to translation tables for a multiprocessor

The same code sequence can be used in a multiprocessing system. The ARMv8 architecture requires a PE that executes a TLB maintenance instruction to execute a `DSB` instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

The completion of a `DSB` that completes a TLB maintenance instruction ensures that all accesses that used the old mapping have completed.

AArch32

P1

```
STR R11, [R1]         ; updates the translation table entry
DSB                   ; ensures visibility of the update to translation table walks
TLBIMVAIS R10
BPIALLIS
DSB                   ; ensures completion of the BP and TLB invalidation
ISB                   ; Note ISB is not broadcast and must be executed locally
                      ; on other PEs
;  new translation table entry can be relied upon at this point and all accesses
;  generated by any observers affected by the broadcast TLBIMVAIS operation using
;  the old mapping have been completed
```

AArch64

P1

```
STR X11, [X1]         ; updates the translation table entry
DSB ISH               ; ensures visibility of the update to translation table walks
TLBI VAE1IS,  X10
DSB ISH               ; ensures completion of the TLB invalidation
ISB                   ; Note ISB is not broadcast and must be executed locally
                      ; on other PEs
;  new translation table entry can be relied upon at this point and all accesses
;  generated by any observers affected by the broadcast TLBIMVAIS operation using
;  the old mapping have been completed
```

The completion of the TLB maintenance instruction is guaranteed only by the execution of a `DSB` by the observer that performed the TLB maintenance instruction. The execution of a `DSB` by a different observer does not have this effect, even if the `DSB` is known to be executed after the TLB maintenance instruction is observed by that different observer.

Paging memory in and out

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the `DSB` that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

AArch32

P1

```
STR R11, [R1]         ; updates the translation table for the region being paged out
DSB                   ; ensures visibility of the update to translation table walks
TLBIMVAIS R10         ; invalidates the old entry
DSB                   ; ensures completion of the invalidation on all PEs
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

```
ISB                  ; ensures visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB                  ; ensures completion of the memory transfer (this could be part of
                     ; LoadMemoryFromBackingStore)
ICIALLUIS            ; also invalidates the branch predictor
STR R9, [R1]         ; creates a new translation table entry with a new mapping
DSB                  ; ensures completion of the instruction cache
                     ; and branch predictor invalidation
                     ; AND ensures visibility of the new translation table mapping
ISB                  ; ensures synchronisation of this instruction stream
```

AArch64

P1

```
STR X11, [X1]        ; updates the translation table for the region being paged out
DSB ISH              ; ensures visibility of the update to translation table walks
TLBI VAE1IS, X10     ; invalidates the old entry
DSB ISH              ; ensures completion of the invalidation on all PEs
ISB                  ; ensures visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB ISH              ; ensures completion of the memory transfer (this could be part of
                     ; LoadMemoryFromBackingStore)
IC IALLUIS           ; also invalidates the branch predictor
STR X9, [X1]         ; creates a new translation table entry with a new mapping
DSB ISH              ; ensures completion of the instruction cache
                     ; and branch predictor invalidation
                     ; AND ensures visibility of the new translation table mapping
ISB                  ; ensures synchronisation of this instruction stream
```

This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of `SaveMemoryPageToBackingStore` and `LoadMemoryFromBackingStore`. `LoadMemoryFromBackingStore` is required to ensure that the memory updates that it makes are visible to instruction fetches.

In this example, the use of ICIALLUIS in AArch32 and IC IALLUIS in AArch64 to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using ICIMVAU and IC IVAU operations in AArch32 and AArch64 respectively. This invalidation must be done when the mapping used for the ICIMVAU and IC IVAU operations is valid but not executable.

Break-before-make updates to translation table entries

The ARM Architecture requires that reads to the same location are observed in order, and since application level software relies on this behavior, the operating system needs to maintain this illusion when it is changing a virtual to physical address mapping for a location, as is the case with copy on write or other memory management techniques. This illusion can be maintained provided that the software uses a break-before-make approach whenever multiple threads of execution can use the same translation tables and the change to the translation entries involves any of:

- Changing the memory type.
- Changing the cacheability attributes
- Changing the output address (OA), if the OA of at least one of the old translation table entry and the new translation table entry is writable.

If software does not use a break-before-make approach, the architecture permits an implementation to give a result which would occur if the two reads to the same virtual address do not occur in program order. An example of such an occurrence would be an implementation of copy-on-write, where one PE is performing two reads to the same virtual address at the same time as a second PE, running code associated with the operating system, is copying the data from one physical location that is mapped to by that virtual address, where the page was mapped as read-only, to a different physical location which will be mapped as read-write.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

If the operating system changes the address mapping without going via an invalid entry, then it is possible for a third PE to perform a write to the location that will be seen by the first load by the first PE, and not seen by the second load by the same PE.

The sequence of code required to perform break-before-make in this case is:

AArch32

P1

```
; R1, R2 contain an invalid translation table entry (that is, one with bit[0] == 0)
; R3 contains the address of the translation table entry
; R4 contains the Virtual Address and ASID of the VA being remapped
; R5, R6 contain the new valid translation table entry
STRD R1, R2, [R3]          ; stores invalid entry
DSB ISH                    ; ensures visibility of the update to translation table walks
TLBIMVAIS R4               ; invalidates the old entry
DSB ISH                    ; ensures completion of the invalidation on all PEs
ICIALLUIS                  ; also invalidates the branch predictor
STRD R5, R6, [R3]          ; store new mapping
DSB ISH                    ; ensures visibility of the update to translation table walks
ISB                        ; ensures synchronisation of this instruction stream
```

Note

This example shows an update to an entry in a translation table that is using the long-descriptor format.

AArch64

P1

```
; X1 contains an invalid translation table entry (that is, one with bit[0] == 0)
; X2 contains the address of the translation table entry
; X3 contains the Virtual Address and ASID of the VA being remapped
; X4 contains the new valid translation table entry
STR X1, [X2]               ; stores invalid entry
DSB ISH                    ; ensures visibility of the update to translation table walks
TLBI VAE1IS, X3            ; invalidates the old entry
DSB ISH                    ; ensures completion of the invalidation on all PEs
IC IALLUIS                 ; also invalidates the branch predictor
STR X4, [X2]               ; store new mapping
DSB ISH                    ; ensures visibility of the update to translation table walks
ISB                        ; ensures synchronisation of this instruction stream
```

If this sequence is correctly followed, then the architecture guarantees that the loads to a virtual address being remapped will be seen in the correct order.

The instruction cache maintenance is only required if the mapping from input address to output address has been changed as part of the change of the translation table entries, and the memory being moved is executable. In this example, the use of `ICIALLUIS` in AArch32 state and `IC IALLUIS` in AArch64 state to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using `ICIMVAU` in AArch32 state, and `IC IVAU` in AArch64 state. This invalidation must be done when the mapping used for the `ICIMVAU` and `IC IVAU` operations is valid but not executable.

K10.5.4 Ordering of Memory-mapped device control with payloads

With a Memory-mapped peripheral, such as a DMA, which can also access memory for its own use, it is common to have control or status registers which are Memory-mapped. These registers need to be accessed in an ordered manner with respect to the data that the Memory-mapped peripheral is handling.

Two simple examples of this are:

- When a processing element is writing a buffer of data, and then writing to a control register in the DMA peripheral to start that peripheral to access the buffer of data.
- When a DMA peripheral has written to a buffer of data in memory, and the processing element is reading a status register to determine that the DMA transfer has completed, and then is reading the data.

For the case of the processing element writing a buffer of data, before starting the DMA peripheral, the ordering requirements between the stores to the data buffer and the stores to the Memory-mapped a to the DMA peripheral can be met by the insertion of a `DSB <domain>` instruction between these sets of accesses as this ensures the global observation of the stores before the DMA is started. this is shown by the following code:

AArch32

P1

```
STR R5, [R2]          ; data written to the data buffer
DSB
STR R0, [R4]          ; R4 contains the address of the DMA control register
```

AArch64

P1

```
STR W5, [X2]          ; data written to the data buffer
DSB <domain>
STR W0, [X4]          ; X4 contains the address of the DMA control register
```

For the case of DMA peripheral writing the data buffer and then setting a status register when those stores are complete (and so globally observed) and then having this status register polled by the processing element before the processing element reads the data buffer, the processing element must insert a `DSB <domain>` between the load that reads the status register, and the read of the buffer. A DMB, or load-acquire, is not sufficient as this problem is not solely concerned with observation order, since the polling read is actually a read of a status register at a slave, not the polling a data value that has been written by an observer.

For this case, the code is therefore:

AArch32

P1

```
WAIT ([R4] == 1)      ; R4 contains the address of the status register,
                      ; and the value '1' indicates completion of the DMA transfer
DSB
LDR R5, [R2]          ; reads data from the data buffer
```

AArch64

P1

```
WAIT ([X4] == 1)      ; X4 contains the address of the status register,
                      ; and the value '1' indicates completion of the DMA transfer
DSB <domain>
LDR W5, [X2]          ; reads data from the data buffer
```

K10.6 ARMv7 compatible approaches for ordering, using DMB and DSB barriers

The following sections describe the ARMv7 compatible approaches for ordering, using DMB and DSB barriers:

- *Simple ordering and barrier cases*.
- *Load-Exclusive, Store-Exclusive and barriers* on page K10-5504.
- *Using a mailbox to send an interrupt* on page K10-5506.
- *Cache and TLB maintenance instructions and barriers* on page K10-5506.

K10.6.1 Simple ordering and barrier cases

ARM implements a weakly consistent memory model for Normal memory. In general terms, this means that the order of memory accesses observed by other observers might not be the order that appears in the program, for either loads or stores.

This section includes examples of this.

Simple weakly consistent ordering example

P1

```
STR R5, [R1]
LDR R6, [R2]
```

P2

```
STR R6, [R2]
LDR R5, [R1]
```

In the absence of barriers, the result of P1: R6=0, P2: R5=0 is permissible.

Message passing

The following sections describe:

- *Weakly-ordered message passing problem*.
- *Message passing with multiple observers* on page K10-5500.

Weakly-ordered message passing problem

P1

```
STR R5, [R1]            ; sets new data
STR R0, [R2]            ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1)           ; waits on flag
LDR R5, [R1]            ; reads new data
```

In the absence of barriers, an end result of P2: R5=0 is permissible.

Resolving by the addition of barriers

The addition of barriers, to ensure the observed order of the reads and the writes, ensures that data is transferred so that the result P2:R5==0x55 is guaranteed, as follows:

P1

```
STR R5, [R1]            ; sets new data
DMB [ST]                ; ensures all observers observe data before the flag
STR R0, [R2]            ; sends flag indicating data ready
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

P2

```
WAIT([R2]==1)           ; waits on flag
DMB                     ; ensures that the load of data is after the flag has been observed
LDR R5, [R1]
```

Resolving by the use of barriers and address dependency

There is a rule within the ARM architecture that:

- Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, then these two memory accesses are observed in program order.

  Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, this is called an *address dependency*. An address dependency exists even if the value returned by the first read has no effect on the virtual address. This might occur if the value returned is masked off before it is used, or if it confirms a predicted address value that it might have changed.

  This restriction applies only when the data value returned by a read is used as a data value to calculate the address of a subsequent read or write. It does not apply if the data value returned by a read determines the condition flags values, and the values of the flags are used for condition code evaluation to determine the address of a subsequent read, either through conditional execution or the evaluation of a branch. This is called a *control dependency*.

  Where both a control and address dependency exist, the ordering behavior is consistent with the address dependency.

Table K10-1 shows examples of address dependencies, control dependencies, and an address and control dependency.

Table K10-1 Dependency examples

Address dependency		**Control dependency**		**Address and control dependency[a]**
(a)	**(b)**	**(c)**	**(d)**	**(e)**
`LDR r1, [r0]`	`LDR r1, [r0]`	`LDR r1, [r0]`	`LDR r1, [r0]`	`LDR r1, [r0]`
`LDR r2, [r1]`	`AND r1, r1, #0`	`CMP r1, #55`	`CMP r1, #55`	`CMP r1, #0`
	`LDR r2, [r3, r1]`	`LDRNE r2, [r3]`	`MOVNE r4, #22`	`LDRNE r2, [r1]`
			`LDR r2, [r3, r4]`	

a. The address dependency takes priority.

This means that the data transfer example of *Weakly-ordered message passing problem* on page K10-5498 can also be satisfied as shown in the following example:

P1

```
STR R5, [R1]            ; sets new data
DMB [ST]                ; ensures all observers observe data before the flag
STR R0, [R2]            ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1)
AND R12, R12, #0        ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12]       ; the load has an address dependency on R12
                        ; and so is ordered after the flag has been seen
```

The load of R5 by P2 is ordered with respect to the load from [R2] because there is an address dependency using R12. P1 uses a `DMB` to ensure that P2 does not observe the write of [R2] before the write of [R1].

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Message passing with multiple observers

Where the ordering of Normal memory accesses is not resolved by the use of barriers or dependencies, then different observers might observe the accesses in a different order, as shown in the following example:

P1

```
STR R5, [R1]            ; sets new data

STR R0, [R2]            ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1)
AND R12, R12, #0        ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12]       ; the load has an address dependency on R12
                        ; and so is ordered after the flag has been seen
```

P3

```
WAIT([R2]==1)
AND R12, R12, #0        ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12]       ; the load is address depndent on R12
                        ; and so is ordered after the flag has been seen
```

In this case, it is permissible for P2:R5 and P3:R5 to contain different values, because there is no order guaranteed between the two stores performed by P1.

Resolving by the addition of barriers

The addition of a barrier by P1, as shown in the following example, ensures the observed order of the writes, transferring data so that P2:R5 and P3:R5 both contain the value `0x55`:

P1

```
STR R5, [R1]            ; sets new data
DMB [ST]                ; ensures all observers observe data before the flag
STR R0, [R2]            ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1)
AND R12, R12, #0        ; R12 is the destination of LDR in WAIT macro
LDR R5, [R1, R12]       ; the load has an address dependency on R12
                        ; and so is ordered after the flag has been seen
```

P3

```
WAIT([R2]==1)
AND R12, R12, #0        ; R12 is the destination of LDR in WAIT macro
LDR R5, [R1, R12]       ; the load has an address dependency on R12
                        ; and so is ordered after the flag has been seen
```

Address dependency with object construction

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object:

P1

```
STR R5, [R1, #offset]   ; sets new data in a field
DMB [ST]                ; ensures all observers observe data before base address is updated
STR R1, [R2]            ; updates base address
```

P2

```
LDR R1, [R2]            ; reads for base address
CMP R1, #0              ; checks if it is valid
BEQ null_trap
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

```
    LDR R5, [R1, #offset]    ; uses base address to read field
```

If the null_trap is not taken, it is required that P2:R5==0x55. This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not require a barrier to ensure this behavior.

P1 requires a barrier to ensure the observed order of the writes by P1. In general, the impact of requiring a barrier during the construction phase is much less than the impact of requiring a barrier for every read access.

Causal consistency issues with multiple observers

The fact that different observers can observe memory accesses in different orders extends, in the absence of barriers, to behaviors that do not fit naturally expected causal properties, as the following example shows:

P1

```
    STR R0, [R2]             ; sets new data
```

P2

```
    WAIT([R2]==1)            ; waits to see new data from P1
    STR R0, [R3]             ; sends flag, must be after the new data has been by P2 as stores,
                             ; must not be speculative
```

P3

```
    WAIT([R3]==1)            ; waits for P2 flag
    AND R12, R12, #0         ; dependency to ensure order
    LDR R0, [R2, R12]        ; reads P1's data
```

In this example, P3:R0==0 is permissible. P3 is not guaranteed to seethe stores from P1 and P2 in any particular order. This applies despite the fact that the store from P2 can only happen after P2 has observed the store from P1.

This example shows that the ARM memory order model for Normal memory does not conform to c*ausal consistency*. This means that the apparently transitive causal relationship between two variables is not guaranteed to be transitive.

The following example shows the insertion of a barrier by P2 to create causal consistency:

P1

```
    STR R0, [R2]             ; sets new data
```

P2

```
    WAIT([R2]==1)            ; waits to see new data from P1
    DMB                      ; ensures P1 data is observed by all observers before any following store
    STR R0, [R3]             ; sends flag
```

P3

```
    WAIT([R3]==1)            ; waits for P2 flag
    AND R12, R12, #0         ; dependency to ensure order
    LDR R0, [R2, R12]        ; reads P1 data
```

This creates causal consistency because a DMB is required to order all accesses that the executing PE observed before the DMB, not only those it issued, before any of the accesses that follow the DMB.

Multiple observers of writes to multiple locations

The ARM weakly consistent memory model means that different observers can observe writes to different locations in different orders, as the following example shows:

P1

```
    STR R0, [R1]             ; sets new data
```

P2

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

```
    STR R0, [R2]             ; sets new data
```

P3

```
    LDR R10, [R2]            ; reads P2 data before P1 data
    LDR R9, [R1]             ;
    BIC R9, R10, R9          ; R9 <- R10 && ~R9
                             ; R9 contains 1 iff read from [R2] is observed to be 1 and
                             ; read from [R1] is observed to be 0.
```

P4

```
    LDR R9, [R1]
    LDR R10, [R2]
    BIC  R9, R9, R10         ; R9 <- R9 && ~R10
                             ; R9 contains 1 iff read from [R2] is observed to be 0 and
                             ; read from [R1] is observed to be 1.
```

In this example, the result P3:R9==1 and P4:R9==1 is permissible. This means that P3 and P4 observed the stores from P1 and P2 in different orders.

The following example shows the use of `DMB` instructions to ensure sequential consistency:

P1

```
    STR R0, [R1]             ; sets new data
```

P2

```
    STR R0, [R2]             ; sets new data
```

P3

```
    LDR R10, [R2]            ; reads P2 data before P1 data
    DMB
    LDR R9, [R1]
    BIC R9, R10, R9          ; R9 <- R10 && ~R9
                             ; R9 contains 1 iff read from [R2] is observed to be 1 and
                             ; read from [R1] is observed to be 0.
```

P4

```
    LDR R9, [R1]             ; reads P1 data before P2 data
    DMB
    LDR R10, [R2]
    BIC  R9, R9, R10         ; R9 <- R9 && ~R10
                             ; R9 contains 1 iff read from [R2] is observed to be 0 and
                             ; read from [R1] is observed to be 1.
```

In this example:

- The `DMB` executed by P3 ensures that, if the P3 load from [R2] observes the P2 store to [R2], then all observers observe the P2 store to [R2] before they observe the P3 load from [R1].
- The `DMB` executed by P4 ensures that, if the P4 load from [R1] observes the P1 store to [R1], then all observers observe the P1 store to [R1 before they observe the P4 load from [R2].

If the P3 load from [R1] returns 0, then it has not observed the P1 store to [R1]. Also, if the P3 load of [R2] returns 1, then all observers must have observed the P2 store to [R2] before they observed the P1 store to [R1]. This means that P4 cannot observe the P1 store to [R1] without also observing the P2 store to [R2].

Alternatively, if the P4 load from [R2] returns 0, then it has not observed the P2 store to [R2]. If, also, the P4 load of [R1] returns 1, then all observers must have observed the P1 store to [R1] before they observed the P2 store to [R2]. This means that P3 cannot observe the P2 store to [R2] without also observing the P1 store to [R1].

This shows that, of the four possible results for {P3:R9, P4:R9}, the insertion of these barriers makes the result {1, 1} impossible.

Posting a store before polling for acknowledgement

In the case where an observer stores to a location, and then polls for an acknowledge from a different observer, the weak ordering of the memory model can lead to a deadlock, as the following example shows:

P1

```
STR R0, [R2]
WAIT ([R3]==1)
```

P2

```
WAIT ([R2]==1)
STR R0, [R3]
```

In ARMv7 implementations that do not include the Multiprocessing Extensions, then this can deadlock because P2 might not observe the store by P1 in finite time. For ARMv7 implementations with the Multiprocessing Extensions and for ARMv8, this is not an issue as all stores must be observed by all observers within their shareability domain in finite time.

The addition of a `DMB` instruction prevents this deadlock in ARMv7 implementations that do not include the Multiprocessing Extensions:

P1

```
STR R0, [R2]
DMB
WAIT ([R3]==1)
```

P2

```
WAIT ([R2]==1)
STR R0, [R3]
```

The `DMB` executed by P1 ensures that P2 observes the store by P1 before it observes the load by P1. This ensures a timely completion.

The following example is a variant of the previous example, where the two observers poll the same memory location:

P1

```
STR R0, [R2]
WAIT ([R2]==2)
```

P2

```
WAIT ([R2]==1)
LDR R0, [R2]
ADD R0, R0, #1
STR R0, [R2]
```

In this example, the same deadlock can occur in ARMv7 implementations that do not include the Multiprocessing Extensions, because the architecture permits P1 to read the result of its own store to [R2] early, and continue doing so for an indefinite amount of time. The addition of a `DMB` instruction prevents this deadlock:

P1

```
STR R0, [R2]
DMB
WAIT ([R2]==2)
```

P2

```
WAIT ([R2]==1)
LDR R0, [R2]
ADD R0, R0, #1
STR R0, [R2]
```

WFE and WFI and barriers

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. A DSB barrier instruction is required if it is necessary to ensure that memory accesses made before the WFI or WFE are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanism that would guarantee the required visibility are the DMB described in *Posting a store before polling for acknowledgement* on page K10-5503, or a dependency on a load.

The following example requires the DSB to ensure that the store is visible:

P1

```
    STR R0, [R2]
    DSB
Loop
    WFI
    B Loop
```

However, if the example in *Posting a store before polling for acknowledgement* on page K10-5503 is extended to include a WFE, there is no risk of a deadlock. The extended example is:

P1

```
    STR R0, [R2]
    DMB
Loop
    LDR R12, [R3]
    CMP R12, #1
    WFENE
    BNE Loop
```

P2

```
    WAIT ([R2]==1)
    STR R0, [R3]
    DSB
    SEV
```

In this example:

- The DMB by P1 ensures that P2 observes the store by P1 before it observes the load by P1.
- The dependency of the WFE on the result of the load by P1 means that this load must complete before P1 executes the WFE.

For more information about SEV, see *Use of Wait For Event (WFE) and Send Event (SEV) with locks* on page K10-5505.

K10.6.2 Load-Exclusive, Store-Exclusive and barriers

The Load-Exclusive and Store-Exclusive instructions, described in *Synchronization and semaphores* on page B2-107, are predictable only with Normal memory. These instructions do not have any implicit barrier functionality. Therefore, any use of these instructions to implement locks of any type requires the addition of explicit barriers.

Acquiring a lock

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.

The lack of implicit barriers in the Load-Exclusive and Store-Exclusive instructions means that the mechanism requires a DMB instruction between acquiring a lock and making the first access to the critical region, to ensure that all observers observe the successful claim of the lock before they observe any subsequent loads or stores to the region. This example shows Px acquiring a lock:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

P*x*

```
Loop
    LDREX R5, [R1]           ; reads lock
    CMP R5, #0               ; checks if 0
    STREXEQ R5, R0, [R1]     ; attempts to store new value
    CMPEQ R5, #0             ; tests if store succeeded
    BNE Loop                 ; retries if not
    DMB                      ; ensures that all subsequent accesses are observed after the
                             ; gaining of the lock is observed
    ; loads and stores in the critical region can now be performed
```

Releasing a lock

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, a `DMB` usually precedes the lock release, as the following example shows.

P*x*

```
    ; loads and stores in the critical region
    MOV R0, #0
    DMB                      ; ensures all previous accesses are observed before the lock is cleared
    STR R0, [R1]             ; clears the lock
```

Use of Wait For Event (WFE) and Send Event (SEV) with locks

The ARMv8 architecture includes Wait For Event and Send Event instructions, that can be executed to reduce the required number of iterations of a lock-acquire loop, or *spinlock*, to reduce power. The basic mechanism involves an observer that is in a spinlock executing a `WFE` instruction that suspends execution on that observer until an asynchronous exception or an explicit event, sent by some other observer using the `SEV` instruction, is seen by the suspended observer. An observer that holds the lock executes an `SEV` instruction to send an event after it has released the lock.

The Event signal is a non-memory communication, and therefore the memory update that releases the lock must be observable by all observers before the `SEV` instruction is executed and the event is sent. This requires the use of `DSB` instruction, rather than `DMB`.

Therefore, the following is an example of lock acquire code using `WFE`:

P*x*

```
Loop
    LDREX R5, [R1]           ; reads lock
    CMP R5, #0               ; checks if 0
    WFENE                    ; sleeps if the lock is held
    STREXEQ R5, R0, [R1]     ; attempts to store new value
    CMPEQ R5, #0             ; tests if store succeeded
    BNE Loop                 ; retries if not
    DMB                      ; ensures that all subsequent accesses are observed after the
                             ; gaining of the lock is observed
    ; loads and stores in the critical region can now be performed
```

And the following is an example of lock release code using `SEV`:

P*x*

```
    ; loads and stores in the critical region
    MOV R0, #0
    DMB                      ; ensures all previous accesses are observed before the lock is cleared
    STR R0, [R1]             ; clears the lock
    DSB                      ; ensures completion of the store that cleared the lock before
                             ; sending the event
    SEV
```

K10.6.3 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a DSB instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

P1

```
STR R5, [R1]            ; message stored to shared memory location
DSB [ST]
STR R1, [R4]            ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR R5, [R1]
```

Note

The DSB executed by P1 ensures global observation of the store to [R1].The interrupt timing ensures that the code executed by P2 is executed after the global observation of the update to [R1], and therefore must see this update. In some implementations, this might be implemented by requiring that interrupts flush non-coherent buffers that hold speculatively loaded data.

K10.6.4 Cache and TLB maintenance instructions and barriers

The following sections describe the use of barriers with cache and TLB maintenance instructions:

- *Data cache maintenance instructions*.
- *Instruction cache maintenance instructions* on page K10-5508.
- *TLB maintenance instructions and barriers* on page K10-5510.

Data cache maintenance instructions

The following sections describe the use of barriers with data cache maintenance instructions:

- *Message passing to non-caching observers*.
- *Multiprocessing message passing to non-caching observers* on page K10-5507.
- *Invalidating DMA buffers, non-functional example* on page K10-5507.
- *Invalidating DMA buffers, functional example with single PE* on page K10-5507.
- *Invalidating DMA buffers, functional example with multiple coherent PEs* on page K10-5508.

Message passing to non-caching observers

The ARMv8 architecture requires the use of DMB instructions to ensure the ordering of data cache maintenance instructions and their effects. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

P1

```
STR R5, [R1]            ; updates data (assumed to be in P1's cache)
DCCMVAC R1              ; cleans cache to point of coherency
DMB                     ; ensures effects of the clean will be observed before the flag is set
STR R0, [R4]            ; sends flag to external agent (Non-cacheable location)
```

E1

```
WAIT ([R4] == 1)        ; waits for the flag
DMB                     ; ensures that flag has been seen before reading data
LDR R5, [R1]            ; reads the data
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

In this example, it is required that E1:R5==0x55.

Multiprocessing message passing to non-caching observers

The broadcast nature of the cache maintenance instructions in ARMv8, and in ARMv7 implementations that include the Multiprocessing Extensions, combined with properties of barriers, means that the message passing principle for non-caching observers is:

P1

```
STR R5, [R1]            ; updates data (assumed to be in P1's cache)
DMB [ST]                ; ensures new data is observed before the flag to P2 is set
STR R0, [R2]            ; sends flag to P2
```

P2

```
WAIT ([R2] == 1)        ; waits for flag from P1
DMB                     ; ensures cache clean is observed after P1 flag is observed
DCCMVAC R1              ; cleans cache to point of coherency - this cleans the cache of P1
DMB                     ; ensures effects of the clean are observed before the flag to E1 is set
STR R0, [R4]            ; sends flag to E1
```

E1

```
WAIT ([R4] == 1)        ; waits for flag from P2
DMB                     ; ensures that flag has been observed before reading the data
LDR R5, [R1]            ; reads the data
```

In this example, it is required that E1:R5==0x55. The clean operation executed by P2 affects the data location in the P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

Invalidating DMA buffers, non-functional example

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable memory region must take account of the architectural requirement that regions marked as Cacheable can be allocated into a cache at any time, for example as a result of speculation. The following example shows this possibility:

P1

```
DCIMVAC R1              ; ensures caches are not dirty. A clean operation could be
                        ; used but the DMA overwrites this region so an invalidate operation
                        ; is sufficient and usually more efficient
DMB                     ; ensures cache invalidation is observed before the next store is observed
STR R0, [R3]            ; sends flag to external agent
WAIT ([R4]==1)          ; waits for a different flag from an external agent
DMB                     ; observes flag from external agent before reading new data. However [R1]
                        ; could have been brought into cache earlier
LDR R5, [R1]
```

E1

```
WAIT ([R3] == 1)        ; waits for flag
STR R5, [R1]            ; stores new data
DMB
STR R0, [R4]            ; sends a flag
```

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.

Invalidating DMA buffers, functional example with single PE

P1

```
DCIMVAC R1              ; ensures cache is not dirty. A clean operation could be
                        ; used but the DMA overwrites this region so an invalidate operation
                        ; is sufficient and usually more efficient
DMB                     ; ensures cache invalidation is observed before the next store is observed
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

```
    STR R0, [R3]            ; sends flag to external agent
    WAIT ([R4]==1)          ; waits for a different flag from an external agent
    DMB                     ; ensures that cache invalidate is observed after the flag
                            ; from external agent is observed
    DCIMVAC R1              ; ensures cache discards stale copies before use
    LDR R5, [R1]
```

E1

```
    WAIT ([R3] == 1)        ; waits for flag
    STR R5, [R1]            ; stores new data
    DMB [ST]
    STR R0, [R4]            ; sends a flag
```

In this example, the result P1:R5 == `0x55` is required. Including a cache invalidation after the store by E1 to [R1] is observed ensures that the line is fetched from external memory after it has been updated.

Invalidating DMA buffers, functional example with multiple coherent PEs

The broadcasting of cache maintenance instructions, and the use of `DMB` instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

P0

```
    (Use data from [R1], potentially using [R1] as scratch space)
    DMB
    STR R0, [R2]            ; signals release of [R1]
    WAIT ([R2] == 0)        ; waits for new value from DMA
    DMB
    LDR R5, [R1]
```

P1

```
    WAIT ([R2] == 1)        ; waits for release of [R1] by P0
    DCIMVAC R1              ; ensures caches are not dirty, invalidate is sufficient
    DMB
    STR R0, [R3]            ; requests new data for [R1]
    WAIT ([R4] == 1)        ; waits for new data
    DMB
    DCIMVAC R1              ; ensures caches discard stale copies before use
    DMB
    MOV R0, #0
    STR R0, [R2]            ; signals availability of new [R1]
```

E1

```
    WAIT ([R3] == 1)        ; waits for new data request
    STR R5, [R1]            ; sends new [R1]
    DMB [ST]
    STR R0, [R4]            ; indicates new data available to P1
```

In this example, the result P0:R5 == `0x55` is required. The `DMB` issued by P1 after the first data cache invalidation ensures that effect of the cache invalidation on P0 is seen by E1 before the store by E1 to [R1]. The `DMB` issued by P1 after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in [R2].

Instruction cache maintenance instructions

The following sections describe the use of barriers with instruction cache maintenance instructions:

- *Ensuring the visibility of updates to instructions for a uniprocessor* on page K10-5509.
- *Ensuring the visibility of updates to instructions for a multiprocessor* on page K10-5509.

Non-Confidential - Beta

Ensuring the visibility of updates to instructions for a uniprocessor

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a `DSB` instruction.

Also, instruction cache maintenance instructions are only guaranteed to complete after the execution of a `DSB`, and an `ISB` is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

P1

```
STR R11, [R1]           ; R11 contains a new instruction to store in program memory
DCCMVAU R1              ; clean to PoU makes new instructions visible to instruction cache
DSB
ICIMVAU R1              ; ensures instruction cache and branch predictor discard stale data
BPIMVA R1
DSB                     ; ensures completion of the invalidation
ISB                     ; ensures instruction fetch path observes new instruction cache state
BX R1
```

Ensuring the visibility of updates to instructions for a multiprocessor

ARMv8, and an ARMv7 implementation that includes the Multiprocessing Extensions, requires a PE that executes an instruction cache maintenance instruction to execute a `DSB` instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

An `ISB` is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own `ISB` synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:

P1

```
STR R11, [R1]           ; R11 contains a new instruction to store in program memory
DCCMVAU R1              ; clean to PoU makes new instructions visible to instruction cache
DSB                     ; ensures completion of the clean on all processors
ICIMVAU R1              ; ensures instruction cache/branch predictor discards stale data
BPIMVA R1
DSB                     ; ensures completion of the instruction cache and branch predictor
                        ; invalidation on all PEs
STR R0, [R2]            ; sets flag to signal completion
ISB                     ; synchronizes context on this PE
BX R1                   ; branches to new code
```

P2-P*x*

```
WAIT ([R2] == 1)        ; waits for flag signaling completion
ISB                     ; synchronizes context on this processor
BX R1                   ; branches to new code
```

Nonfunctional approach

The following sequence does not have the same effect, because a `DSB` is not required to complete the instruction cache maintenance instructions that other PEs issue:

P1

```
STR R11, [R1]           ; R11 contains a new instruction to store in program memory
DCCMVAU R1              ; clean to PoU makes new instructions visible to instruction cache
DSB                     ; ensure completion of the clean on all PEs
ICIMVAU R1              ; ensure instruction cache/branch predictor discards stale data
BPIMVA R1
DMB                     ; ensure ordering of the store after the invalidation
                        ; DOES NOT guarantee completion of instruction cache/branch
                        ; predictor on other PEs
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

```
    STR R0, [R2]            ; sets flag to signal completion
    DSB                     ; ensures completion of the invalidation on all PEs
    ISB                     ; synchronizes context on this PE
    BX R1                   ; branches to new code
```

P2-P*x*

```
    WAIT ([R2] == 1)        ; waits for flag signaling completion
    DSB                     ; this DSB does not guarantee completion of P1's ICIMVAU/BPIMVA
    ISB
    BX R1
```

In this example, P2…P*x* might not see the updated region of code at R1.

TLB maintenance instructions and barriers

The following sections describe the use of barriers with TLB maintenance instructions:

- *Ensuring the visibility of updates to translation tables for a uniprocessor*.
- *Ensuring the visibility of updates to translation tables for a multiprocessor*.
- *Paging memory in and out* on page K10-5511.

Ensuring the visibility of updates to translation tables for a uniprocessor

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a `DSB` instruction.

In the ARMv8 architecture, and in an ARMv7 implementation that includes the Multiprocessing Extensions, translation table walks must look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a `DSB` and an `ISB`. Therefore, the code for updating a translation table entry is:

P1

```
    STR R11, [R1]           ; updates the translation table entry
    DSB                     ; ensures visibility of the update to translation table walks
    TLBIMVA R10
    BPIALL
    DSB                     ; ensures completion of the BP and TLB invalidation
    ISB                     ; synchronizes context on this PE
    ;
    ; new translation table entry can be relied upon at this point and all accesses
    ; generated by this observer using the old mapping have been completed
```

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.

Ensuring the visibility of updates to translation tables for a multiprocessor

The same code sequence can be used in a multiprocessing system. In the ARMv8 architecture, and in an ARMv7 implementation that includes the Multiprocessing Extensions, a PE that executes a TLB maintenance instruction must execute a `DSB` instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

The completion of a `DSB` that completes a TLB maintenance instruction ensures that all accesses that used the old mapping have completed.

P1

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

```
STR R11, [R1]           ; updates the translation table entry
DSB                     ; ensures visibility of the update to translation table walks
TLBIMVAIS R10
BPIALLIS
DSB                     ; ensures completion of the BP and TLB invalidation
ISB                     ; Note ISB is not broadcast and must be executed locally on other PEs
;
; new translation table entry can be relied upon at this point and all accesses generated by any
; observers affected by the broadcast TLBIMVAIS operation using the old mapping have completed
```

The completion of the TLB maintenance instruction is guaranteed only by the execution of a DSB by the observer that performed the TLB maintenance instruction. The execution of a DSB by a different observer does not have this effect, even if the DSB is known to be executed after the TLB maintenance instruction is observed by that different observer.

Paging memory in and out

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the DSB that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

P1

```
STR R11, [R1]           ; updates the translation table for the region being paged out
DSB                     ; ensures visibility of the update to translation table walks
TLBIMVAIS R10           ; invalidates the old entry
DSB                     ; ensures completion of the invalidation on all processors
ISB                     ; ensures visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB                     ; ensures completion of the memory transfer (this could be part of
                        ; LoadMemoryFromBackingStore
ICIALLUIS               ; also invalidates the branch predictor
STR R9, [R1]            ; creates a new translation table entry with a new mapping
DSB                     ; ensures completion of instruction cache and branch predictor invalidation
                        ; and ensures visibility of the new translation table mapping
ISB                     ; ensures synchronization of this instruction stream
```

This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of SaveMemoryPageToBackingStore and LoadMemoryFromBackingStore. LoadMemoryFromBackingStore is required to ensure that the memory updates that it makes are visible to instruction fetches.

In this example, the use of ICIALLUIS to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using ICIMVAU operations. This invalidation must be done when the mapping used for the ICIMVAU operations is valid but not executable.

Appendix K11
ARM Pseudocode Definition

This appendix provides a definition of the pseudocode that is used in this manual, and defines some *helper* procedures and functions that are used by pseudocode. It contains the following sections:

- *About the ARM pseudocode* on page K11-5514.
- *Pseudocode for instruction descriptions* on page K11-5515.
- *Data types* on page K11-5517.
- *Operators* on page K11-5522.
- *Statements and control structures* on page K11-5528.
- *Built-in functions* on page K11-5534.
- *Miscellaneous helper procedures and functions* on page K11-5537.
- *ARM pseudocode definition index* on page K11-5539.

Note

This appendix is not a formal language definition for the pseudocode. It is a guide to help understand the use of ARM pseudocode. This appendix is not complete. Changes are planned for future releases.

K11.1 About the ARM pseudocode

The ARM pseudocode provides precise descriptions of some areas of the ARM architecture. This includes description of the decoding and operation of all valid instructions. *Pseudocode for instruction descriptions* on page K11-6021 gives general information about this instruction pseudocode, including its limitations.

The following sections describe the ARM pseudocode in detail:

- *Data types* on page K11-6023.
- *Operators* on page K11-6028.
- *Statements and control structures* on page K11-6034.

Built-in functions on page K11-6040 and *Miscellaneous helper procedures and functions* on page K11-6043 describe some built-in functions and pseudocode helper functions that are used by the pseudocode functions that are described elsewhere in this manual. *ARM pseudocode definition index* on page K11-6046 contains the indexes to the pseudocode.

K11.1.1 General limitations of ARM pseudocode

The pseudocode statements `IMPLEMENTATION_DEFINED`, `SEE`, `UNDEFINED`, and `UNPREDICTABLE` indicate behavior that differs from that indicated by the pseudocode being executed. If one of them is encountered:

- Earlier behavior indicated by the pseudocode is only specified as occurring to the extent required to determine that the statement is executed.
- No subsequent behavior indicated by the pseudocode occurs.

For more information, see *Special Statements* on page K11-6038.

Non-Confidential - Beta

K11.2 Pseudocode for instruction descriptions

Each instruction description includes pseudocode that provides a precise description of what the instruction does, subject to the limitations described in *General limitations of ARM pseudocode* on page K11-6020 and *Limitations of the instruction pseudocode* on page K11-6022.

In the instruction pseudocode, instruction fields are referred to by the names shown in the encoding diagram for the instruction. *Instruction encoding diagrams and instruction pseudocode* gives more information about the pseudocode provided for each instruction.

K11.2.1 Instruction encoding diagrams and instruction pseudocode

Instruction descriptions in this manual contain:

- An Encoding section, containing one or more encoding diagrams, each followed by some encoding-specific pseudocode that translates the fields of the encoding into inputs for the common pseudocode of the instruction, and picks out any encoding-specific special cases.
- An Operation section, containing common pseudocode that applies to all of the encodings being described. The Operation section pseudocode contains a call to the `EncodingSpecificOperations()` function, either at its start or only after a condition code check performed by `if ConditionPassed() then`.

An encoding diagram specifies each bit of the instruction as one of the following:

- An obligatory 0 or 1, represented in the diagram as 0 or 1. If this bit does not have this value, the encoding corresponds to a different instruction.
- A *should be* 0 or 1, represented in the diagram as (0) or (1). If this bit does not have this value, the instruction is CONSTRAINED UNPREDICTABLE. For more information, see *SBZ or SBO fields in instructions* on page K1-5292.
- A named single bit or a bit in a named multi-bit field. The `cond` field in bits[31:28] of many A32/T32 instructions has some special rules associated with it.

An encoding diagram matches an instruction if all obligatory bits are identical in the encoding diagram and the instruction, and one of the following is true:

- The encoding diagram is not for an A32/T32 instruction.
- The encoding diagram is for an A32/T32 instruction that does not have a `cond` field in bits[31:28].
- The encoding diagram is for an A32/T32 instruction that has a `cond` field in bits[31:28], and bits[31:28] of the instruction are not `0b1111`.

In the context of the instruction pseudocode, the execution model for an instruction is:

1. Find all encoding diagrams that match the instruction. It is possible that no encoding diagram matches. In that case, abandon this execution model and consult the relevant instruction set chapter instead to find out how the instruction is to be treated. The bit pattern of such an instruction is usually reserved and UNDEFINED, though there are some other possibilities. For example, unallocated hint instructions are documented as being reserved and executed as NOPs.
2. If the operation pseudocode for the matching encoding diagrams starts with a condition code check, perform that check. If the condition code check fails, abandon this execution model and treat the instruction as a NOP. If there are multiple matching encoding diagrams, either all or none of their corresponding pieces of common pseudocode start with a condition code check.
3. Perform the encoding-specific pseudocode for each of the matching encoding diagrams independently and in parallel. Each such piece of encoding-specific pseudocode starts with a bitstring variable for each named bit or multi-bit field in its corresponding encoding diagram, named the same as the bit or multi-bit field and initialized with the values of the corresponding bit or bits from the bit pattern of the instruction.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

In a few cases, the encoding diagram contains more than one bit or field with same name. In these cases, the values of the different instances of those bits or fields must be identical. The encoding-specific pseudocode contains a special case using the `Consistent()` function to specify what happens if they are not identical. `Consistent()` returns `TRUE` if all instruction bits or fields with the same name as its argument have the same value, and `FALSE` otherwise.

If there are multiple matching encoding diagrams, all but one of the corresponding pieces of pseudocode must contain a special case that indicates that it does not apply. Discard the results of all such pieces of pseudocode and their corresponding encoding diagrams.

There is now one remaining piece of pseudocode and its corresponding encoding diagram left to consider. This pseudocode might also contain a special case, most commonly one indicating that it is CONSTRAINED UNPREDICTABLE. If so, abandon this execution model and treat the instruction according to the special case.

4. Check the *should be* bits of the encoding diagram against the corresponding bits of the bit pattern of the instruction. If any of them do not match, abandon this execution model and treat the instruction as CONSTRAINED UNPREDICTABLE, see *SBZ or SBO fields in instructions* on page K1-5292.

5. Perform the rest of the operation pseudocode for the instruction description that contains the encoding diagram. That pseudocode starts with all variables set to the values they were left with by the encoding-specific pseudocode.

The `ConditionPassed()` call in the common pseudocode, if present, performs step 2, and the `EncodingSpecificOperations()` call performs steps 3 and 4.

K11.2.2 Limitations of the instruction pseudocode

The pseudocode descriptions of instruction functionality have a number of limitations. These are mainly due to the fact that, for clarity and brevity, the pseudocode is a sequential and mostly deterministic language.

These limitations include:

- Pseudocode does not describe the ordering requirements when an instruction generates multiple memory accesses. For a description of the ordering requirements on memory accesses see *Ordering requirements* on page E2-2267.
- Pseudocode does not describe the exact rules when an UNDEFINED instruction fails its condition code check. In such cases, the `UNDEFINED` pseudocode statement lies inside the `if ConditionPassed() then …` structure, either directly or in the `EncodingSpecificOperations()` function call, and so the pseudocode indicates that the instruction executes as a NOP. *Conditional execution of undefined instructions* on page G1-3686 describes the exact rules.
- Pseudocode does not describe the exact ordering requirements when a single floating-point instruction generates more than one floating-point exception and one or more of those floating-point exceptions is trapped. *Combinations of floating-point exceptions* on page E1-2221 describes the exact rules.

  Note

  There is no limitation in the case where all the floating-point exceptions are untrapped, because the pseudocode specifies the same behavior as the cross-referenced section.

- An exception can be taken during execution of the pseudocode for an instruction, either explicitly as a result of the execution of a pseudocode function such as `Abort()`, or implicitly, for example if an interrupt is taken during execution of an `LDM` instruction. If this happens, the pseudocode does not describe the extent to which the normal behavior of the instruction occurs. To determine that, see the descriptions of the exceptions in *Handling exceptions that are taken to an Exception level using AArch32* on page G1-3647.

K11.3 Data types

This section describes:

- *General data type rules*.
- *Bitstrings*.
- *Integers* on page K11-6024.
- *Reals* on page K11-6024.
- *Booleans* on page K11-6025.
- *Enumerations* on page K11-6025.
- *Tuples* on page K11-6025.
- *Structs* on page K11-6026.
- *Arrays* on page K11-6027.

K11.3.1 General data type rules

ARM architecture pseudocode is a strongly typed language. Every literal and variable is of one of the following types:

- Bitstring.
- Integer.
- Boolean.
- Real.
- Enumeration.
- Tuple.
- Struct.
- Array.

The type of a literal is determined by its syntax. A variable can be assigned to without an explicit declaration. The variable implicitly has the type of the assigned value. For example, the following assignments implicitly declare the variables `x`, `y` and `z` to have types integer, bitstring of length 1, and Boolean, respectively.

```
x = 1;
y = '1';
z = TRUE;
```

Variables can also have their types declared explicitly by preceding the variable name with the name of the type. The following example declares explicitly that a variable named `count` is an integer.

```
integer count;
```

This is most often done in function definitions for the arguments and the result of the function.

The remaining subsections describe each data type in more detail.

K11.3.2 Bitstrings

This section describes the bitstring data type.

Syntax

`bits(N)`	The type name of a bitstring of length `N`.
`bit`	A synonym of `bits(1)`.

Description

A bitstring is a finite-length string of 0s and 1s. Each length of bitstring is a different type. The minimum permitted length of a bitstring is 1.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Bitstring constants literals are written as a single quotation mark, followed by the string of 0s and 1s, followed by another single quotation mark. For example, the two constants literals of type `bit` are `'0'` and `'1'`. Spaces can be included in bitstrings for clarity.

The bits in a bitstring are numbered from left to right *N*-1 to 0. This numbering is used when accessing the bitstring using bitslices. In conversions to and from integers, bit *N*-1 is the MSByte and bit 0 is the LSByte. This order matches the order in which bitstrings derived from encoding diagrams are printed.

Every bitstring value has a left-to-right order, with the bits being numbered in standard *little-endian* order. That is, the leftmost bit of a bitstring of length `N` is bit (*N*–1) and its right-most bit is bit 0. This order is used as the most-significant-to-least-significant bit order in conversions to and from integers. For bitstring constants and bitstrings that are derived from encoding diagrams, this order matches the way that they are printed.

Bitstrings are the only concrete data type in pseudocode, corresponding directly to the contents values that are manipulated in registers, memory locations, and instructions. All other data types are abstract.

K11.3.3 Integers

This section describes the data type for integer numbers.

Syntax

`integer` The type name for the integer data type.

Description

Pseudocode integers are unbounded in size and can be either positive or negative. That is, they are mathematical integers rather than what computer languages and architectures commonly call integers. Computer integers are represented in pseudocode as bitstrings of the appropriate length, and the pseudocode provides functions to interpret those bitstrings as integers.

Integer literals are normally written in decimal form, such as `0`, `15`, `-1234`. They can also be written in C-style hexadecimal form, such as `0x55` or `0x80000000`. Hexadecimal integer literals are treated as positive unless they have a preceding minus sign. For example, `0x80000000` is the integer $+2^{31}$. If -2^{31} needs to be written in hexadecimal, it must be written as `-0x80000000`.

K11.3.4 Reals

This section describes the data type for real numbers.

Syntax

`real` The type name for the real data type.

Description

Pseudocode reals are unbounded in size and precision. That is, they are mathematical real numbers, not computer floating-point numbers. Computer floating-point numbers are represented in pseudocode as bitstrings of the appropriate length, associated with suitable and the pseudocode provides functions to interpret those bitstrings as reals.

Real constants literals are written in decimal form with a decimal point. This means `0` is an integer constant literal, but `0.0` is a real constant literal.

K11.3.5 Booleans

This section describes the Boolean data type.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Syntax

`boolean` The type name for the Boolean data type.

`TRUE` The two values a Boolean variable can take.

Description

A Boolean is a logical `TRUE` or `FALSE` value.

Note

This is not the same type as `bit`, which is a bitstring of length 1. A Boolean can only take on one of two values: `TRUE` or `FALSE`.

K11.3.6 Enumerations

This section describes the enumeration data type.

Syntax and examples

`enumeration` Keyword to defined a new enumeration type.

```
enumeration Example {Example_One, Example_Two, Example_Three};
```

A definition of a new enumeration called `Example`, which can take on the values `Example_One`, `Example_Two`, `Example_Three`.

Description

An enumeration is a defined set of named values.

An enumeration must contain at least one named value. A named value must not be shared between enumerations.

Enumerations must be defined explicitly, although a variable of an enumeration type can be declared implicitly by assigning one of the named values to it. By convention, each named value starts with the name of the enumeration followed by an underscore. The name of the enumeration is its *type name*, or *type*, and the named values are its possible *values*.

K11.3.7 Structures

This section describes the structure data type.

Syntax and examples

`type` The keyword used to declare the structure data type.

```
type ShiftSpec is (bits(2) shift, integer amount)
```

An example definition for a new structure called `ShiftSpec` that contains an bitstring member called `shift` and a integer member named `amount`. Structure definitions must not be terminated with a semicolon.

```
ShiftSpec abc;
```

A declaration of a variable named `abc` of type `ShiftSpec`.

```
abc.shift
```

Syntax to refer to the individual members within the structure variable.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Description

A structure is a compound data type composed of one or more data items. The data items can be of different data types. This can include compound data types. The data items of a structure are called its members and are named.

In the syntax section, the example defines a structure called `ShiftSpec` with two members. The first is a bitstring of length 2 named `shift` and the second is an integer named `amount`. After declaring a variable of that type named `abc`, the members of this structure are referred to as `abc.shift` and `abc.amount`.

Every definition of a structure creates a different type, even if the number and type of their members are identical. For example:

```
type ShiftSpec1 is (bits(2) shift, integer amount)
type ShiftSpec2 is (bits(2) shift, integer amount)
```

`ShiftSpec1` and `ShiftSpec2` are two different types despite having identical definitions. This means that the value in a variable of type `ShiftSpec1` cannot be assigned to variable of type `ShiftSpec2`.

K11.3.8 Tuples

This section describes the tuple data type.

Examples

```
(bits(32) shifter_result, bit shifter_carry_out)
```

An example of the tuple syntax.

```
(shift_t, shift_n) = ('00', 0);
```

An example of assigning values to a tuple.

Description

A tuple is an ordered set of data items, separated by commas and enclosed in parentheses. The items can be of different types and a tuple must contain at least one data item.

Tuples are often used as the return type for functions that return multiple results. For example, in the syntax section, the example tuple is the return type of the function `Shift_C()`, which performs a standard A32/T32 shift or rotation. Its return type is a tuple containing two data items, with the first of type `bits(32)` and the second of type `bit`.

Each tuple is a separate compound data type. The compound data type is represented as a comma-separated list of ordered data types between parentheses. This means that the example tuple at the start of this section is of type `(bits(32), bit)`. The general principle that types can be implied by an assignment extends to implying the type of the elements in the tuple. For example, in the syntax section, the example assignment implicitly declares:

- `shift_t` to be of type `bits(2)`.
- `shift_n` to be of type `integer`.
- `(shift_t, shift_n)` to be a tuple of type `(bits(2), integer)`.

Non-Confidential - Beta

K11.3.9 Arrays

This section describes the array data type.

Syntax

`array` The type name for the array data type.

```
array data_type array_name[A..B];
```

Declaration of an array of type `data_type`, which might be compound data type. It is named `array_name` and is indexed with an integer range from `A` to `B`.

Description

An array is an ordered set of fixed size containing items of a single data type. This can include compound data types. Pseudocode arrays are indexed by either enumerations or integer ranges. An integer range is represented by the lower inclusive end of the range, then `..`, then the upper inclusive end of the range.

For example:

The following example declares an array of 31 bitstrings of length 64, indexed from 0 to 30.

```
array bits(64) _R[0..30];
```

Arrays are always explicitly declared, and there is no notation for a constant literal array. Arrays always contain at least one element data item, because:

- Enumerations always contain at least one symbolic constant named value.
- Integer ranges always contain at least one integer.

An array declared with an enumeration type as the index must be accessed using enumeration values of that enumeration type. An array declared with an integer range type as the index must be accessed using integer values from that inclusive range. Accessing such an array with an integer value outside of the range is a coding error.

Arrays do not usually appear directly in pseudocode. The items that syntactically look like arrays in pseudocode are usually array-like functions such as `R[i]`, `MemU[address, size]` or `Elem[vector, i, size]`. These functions package up and abstract additional operations normally performed on accesses to the underlying arrays, such as register banking, memory protection, endian-dependent byte ordering, exclusive-access housekeeping and Advanced SIMD element processing. See *Function and procedure calls* on page K11-5528.

K11.4 Operators

This section describes:

- *Relational operators*.
- *Boolean operators*
- *Arithmetic operators* on page K11-6029

K11.4.1 Relational operators

The following operations yield results of type `boolean`.

Equality and non-equality

If two variables `x` and `y` are of the same type, their values can be tested for equality by using the expression `x == y` and for non-equality by using the expression `x != y`. In both cases, the result is of type `boolean`.

Both `x` and `y` must be of type `bits(N)`, `real` , `enumeration`, `boolean`, or `integer`. Named values from an `enumeration` can only be compared if they are both from the same `enumeration`. An exception is that a bitstring can be tested for equality with an integer to allow a `d==15` test.

A special form of comparison is defined with a bitstring literal that can contain bit values `'0'` , `'1'`, and `'x'`. Any bit with value `'x'` is ignored in determining the result of the comparison. For example, if `opcode` is a 4-bit bitstring, the expression `opcode == '1x0x'` matches the values `'1000'`, `'1100'`, `'1001'`, and `'1101'`. This is known as a bitmask.

Note

This special form is permitted in the implied equality comparisons in the `when` parts of `case … of …` structures.

Comparisons

If `x` and `y` are integers or reals, then `x < y`, `x <= y`, `x > y`, and `x >= y` are less than, less than or equal, greater than, and greater than or equal comparisons between them, producing Boolean results.

Set membership with `IN`

`<expression> IN {<set>}` produces `TRUE` if `<expression>` is a member of `<set>`. Otherwise, it is `FALSE`. `<set>` must be a list of expressions separated by commas.

K11.4.2 Boolean operators

If `x` is a Boolean expression, then `!x` is its logical inverse.

If `x` and `y` are Boolean expressions, then `x && y` is the result of ANDing them together. As in the C language, if `x` is `FALSE`, the result is determined to be `FALSE` without evaluating `y`.

Note

This is known as short circuit evaluation.

If `x` and `y` are `booleans`, then `x || y` is the result of ORing them together. As in the C language, if `x` is `TRUE`, the result is determined to be `TRUE` without evaluating `y`.

Note

If `x` and `y` are `booleans` or Boolean expressions, then the result of `x != y` is the same as the result of exclusive-ORing `x` and `y` together. The operator `EOR` only accepts bitstring arguments.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

K11.4.3 Bitstring operators

The following operations can be applied only to bitstrings.

Logical operations on bitstrings

If x is a bitstring, NOT(x) is the bitstring of the same length obtained by logically inverting every bit of x.

If x and y are bitstrings of the same length, x AND y, x OR y, and x EOR y are the bitstrings of that same length obtained by logically ANDing, logically ORing, and exclusive-ORing corresponding bits of x and y together.

Bitstring concatenation and slicing

If x and y are bitstrings of lengths N and M respectively, then x:y is the bitstring of length N+M constructed by concatenating x and y in left-to-right order.

The bitstring slicing operator addresses specific bits in a bitstring. This can be used to create a new bitstring from extracted bits or to set the value of specific bits. Its syntax is x<integer_list>, where x is the integer or bitstring being sliced, and <integer_list> is a comma-separated list of integers enclosed in angle brackets. The length of the resulting bitstring is equal to the number of integers in <integer_list>. In x<integer_list>, each of the integers in <integer_list> must be:

- >= 0.
- < Len(x) if x is a bitstring.

The definition of x<integer_list> depends on whether integer_list contains more than one integer:

- If integer_list contains more than one integer, x<i, j, k,…, n> is defined to be the concatenation:

  x<i> : x<j> : x<k> : … : x<n>.

- If integer_list consists of just one integer i, x<i> is defined to be:
  - If x is a bitstring, '0' if bit i of x is a zero and '1' if bit i of x is a one.
  - If x is an integer, and y is the unique integer in the range 0 to 2^(i+1)-1 that is congruent to x modulo 2^(i+1). Then x<i> is '0' if y < 2^i and '1' if y >= 2^i.

    Loosely, this definition treats an integer as equivalent to a sufficiently long two's complement representation of it as a bitstring.

The notation for a range expression is i:j with i >= j is shorthand for the integers in order from i down to j, with both end values included. For example, instr<31:28> represents instr<31, 30, 29, 28>.

x<integer_list> is assignable provided x is an assignable bitstring and no integer appears more than once in <integer_list>. In particular, x<i> is assignable if x is an assignable bitstring and 0 <= i < Len(x).

Encoding diagrams for registers frequently show named bits or multi-bit fields. For example, the encoding diagram for the APSR shows its bit<31> as N. In such cases, the syntax APSR.N is used as a more readable synonym for APSR<31> as named bits can be referred to with the same syntax as referring to members of a struct. A comma-separated list of named bits enclosed in angle brackets following the register name allows multiple bits to be addressed simultaneously. For example, APSR.<N, C, Q> is synonymous with APSR <31, 29, 27>.

K11.4.4 Arithmetic operators

Most pseudocode arithmetic is performed on integer or real values, with operands obtained by conversions from bitstrings and results converted back to bitstrings. As these data types are the unbounded mathematical types, no issues arise about overflow or similar errors.

Unary plus and minus

If x is an integer or real, then +x is x unchanged, -x is x with its sign reversed. Both are of the same type as x.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Addition and subtraction

If x and y are integers or reals, x+y and x-y are their sum and difference. Both are of type `integer` if x and y are both of type `integer`, and `real` otherwise.

There are two cases where the types of x and y can be different. A bitstring and an integer can be added together to allow the operation `PC + 4`. An integer can be subtracted from a bitstring to allow the operation `PC - 2`.

If x and y are bitstrings of the same length N, so that `N = Len(x) = Len(y)`, then x+y and x-y are the least significant *N* bits of the results of converting x and y to integers and adding or subtracting them. Signed and unsigned conversions produce the same result:

```
x+y = (SInt(x) + SInt(y))<N-1:0>
    = (UInt(x) + UInt(y))<N-1:0>
x-y = (SInt(x) - SInt(y))<N-1:0>
    = (UInt(x) - UInt(y))<N-1:0>
```

If x is a bitstring of length N and y is an integer, x+y and x-y are the bitstrings of length N defined by `x+y = x + y<N-1:0>` and `x-y = x - y<N-1:0>`. Similarly, if x is an integer and y is a bitstring of length M, x+y and x-y are the bitstrings of length M defined by `x+y = x<M-1:0> + y` and `x-y = x<M-1:0> - y`.

Multiplication

If x and y are integers or reals, then `x * y` is the product of x and y. It is of type `integer` if x and y are both of type `integer`, and `real` otherwise.

Division and modulo

If x and y are reals, then x/y is the result of dividing x by y, and is always of type `real`.

If x and y are integers, then `x DIV y` and `x MOD y` are defined by:

```
x DIV y = RoundDown(x/y)
x MOD y = x - y * (x DIV y)
```

It is a pseudocode error to use any of x/y, `x MOD y`, or `x DIV y` in any context where y can be zero.

Scaling

If x and n are of type `integer`, then:

- `x << n = RoundDown(x * 2^n)`.
- `x >> n = RoundDown(x * 2^(-n))`.

Raising to a power

If x is an integer or a real and n is an integer then x^n is the result of raising x to the power of n, and:

- If x is of type `integer` then x^n is of type `integer`.
- If x is of type `real` then x^n is of type `real`.

K11.4.5 The assignment operator

The assignment operator is the = character, which assigns the value of the right-hand side to the left-hand side. An assignment statement takes the form:

```
<assignable_expression> = <expression>;
```

This following subsection defines valid expression syntax.

General expression syntax

An expression is one of the following:

- A literal.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- A variable, optionally preceded by a data type name to declare its type.
- The word `UNKNOWN` preceded by a data type name to declare its type.
- The result of applying a language-defined operator to other expressions.
- The result of applying a function to other expressions.

Variable names normally consist of alphanumeric and underscore characters, starting with an alphabetic or underscore character.

Each register defined in an ARM architecture specification defines a correspondingly named pseudocode bitstring variable, and that variable has the stated behavior of the register. For example, if a bit of a register is defined as RAZ/WI, then the corresponding bit of its variable reads as `'0'` and ignore writes.

An expression like `bits(32) UNKNOWN` indicates that the result of the expression is a value of the given type, but the architecture does not specify what value it is and software must not rely on such values. The value produced must not:

- Return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE or `CONSTRAINED UNPREDICTABLE` and do not return UNKNOWN values,
- Be promoted as providing any useful information to software.

Note

UNKNOWN values are similar to the definition of UNPREDICTABLE, but do not indicate that the entire architectural state becomes unspecified.

Only the following expressions are assignable. This means that these are the only expressions that can be placed on the left-hand side of an assignment.

- Variables.
- The results of applying some operators to other expressions.

  The description of each language-defined operator that can generate an assignable expression specifies the circumstances under which it does so. For example, those circumstances might require that one or more of the expressions the operator operates on is an assignable expression.
- The results of applying array-like functions to other expressions. The description of an array-like function specifies the circumstances under which it can generate an assignable expression.

Note

If the right-hand side in an assignment is a function returning a tuple, an item in the assignment destination can be written as - to indicate that the corresponding item of the assigned tuple value is discarded. For example:

```
(shifted, -) = LSL_C(operand, amount);
```

The expression on the right-hand side itself can be a tuple. For example:

```
(x, y) = (function_1(), function_2());
```

Every expression has a data type.

- For a literal, this data type is determined by the syntax of the literal.
- For a variable, there are the following possible sources for the data type
  - — An optional preceding data type name.
  - — A data type the variable was given earlier in the pseudocode by recursive application of this rule.
  - — A data type the variable is being given by assignment, either by direct assignment to the variable, or by assignment to a list of which the variable is a member.

  It is a pseudocode error if none of these data type sources exists for a variable, or if more than one of them exists and they do not agree about the type.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- For a language-defined operator, the definition of the operator determines the data type.
- For a function, the definition of the function determines the data type.

K11.4.6 Precedence rules

The precedence rules for expressions are:

1. Literals, variables and function invocations are evaluated with higher priority than any operators using their results, but see *Boolean operators* on page K11-6028.
2. Operators on integers follow the normal operator precedence rules of *exponentiation before multiply/divide before add/subtract*, with sequences of multiply/divides or add/subtracts evaluated left-to-right.
3. Other expressions must be parenthesized to indicate operator precedence if ambiguity is possible, but need not be if all permitted precedence orders under the type rules necessarily lead to the same result. For example, if `i`, `j` and `k` are integer variables, `i > 0 && j > 0 && k > 0` is acceptable, but `i > 0 && j > 0 || k > 0` is not.

K11.4.7 Conditional expressions

If `x` and `y` are two values of the same type and `t` is a value of type `boolean`, then `if t then x else y` is an expression of the same type as `x` and `y` that produces `x` if `t` is `TRUE` and `y` if `t` is `FALSE`.

K11.4.8 Operator polymorphism

Operators in pseudocode can be polymorphic, with different functionality when applied to different data types. Each resulting form of an operator has a different prototype definition. For example, the operator `+` has forms that act on various combinations of integers, reals and bitstrings.

Table K11-1 summarizes the operand types valid for each unary operator and the result type. Table K11-2 summarizes the operand types valid for each binary operator and the result type.

Table K11-1 Result and operand types permitted for unary operators

Operator	Operand Type	Result Type
-	integer	integer
	real	real
NOT	bits(N)	bits(N)
!	boolean	boolean

Table K11-2 Result and operand types permitted for binary operators

Operator	First operand type	Second operand type	Result type
==	bits(N)	integer	boolean
		bits(N)	
	integer	integer	
	real	real	
	enumeration	enumeration	
	boolean	boolean	
!=	bits(N)	bits(N)	boolean
	integer	integer	
	real	real	
<, >	integer	integer	boolean
<= , >=	real	real

K11.5 Statements and control structures

This section describes the statements and program structures available in the pseudocode.

K11.5.1 Statements and Indentation

A simple statement is either an assignment, a function call, or a procedure call. Each statement must be terminated with a semicolon.

Indentation normally indicates the structure in compound statements. The statements contained in structures such as `if … then … else …` or procedure and function definitions are indented more deeply than the statement structure itself. The end of a compound statement structure and their end is indicated by returning to the original indentation level or less.

Indentation is normally done by four spaces for each level. Standard indentation uses four spaces for each level of indent.

K11.5.2 Function and procedure calls

This section describes how functions and procedures are defined and called in the pseudocode.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Procedure and function definitions

A procedure definition has the form:

```
<procedure name>(<argument prototypes>)
    <statement 1>;
    <statement 2>;
    …
    <statement n>;
```

where `<argument prototypes>` consists of zero or more argument definitions, separated by commas. Each argument definition consists of a type name followed by the name of the argument.

Note

This first definition line is not terminated by a semicolon. This distinguishes it from a procedure call.

A function definition is similar, but also declares the return type of the function:

```
<return type> <function name>(<argument prototypes>)
    <statement 1>;
    <statement 2>;
    …
    <statement n>;
```

Note

A function or procedure name can include a "`.`". This is a convention used for functions that have similar but different behaviors in AArch32 and AArch64 states.

Array-like functions are similar, but are written with square brackets and have two forms. These two forms exist because reading from and writing to an array element require different functions. They are frequently used in memory operations. An array-like function definition with a return type is equivalent to reading from an array. For example:

```
<return type> <function name>[<argument prototypes>]
    <statement 1>;
    <statement 2>;
    …
    <statement n>;
```

Its related function definition with no return type is equivalent to writing to an array. For example:

```
<function name>[<argument prototypes>] = <value prototype>
    <statement 1>;
    <statement 2>;
    …
    <statement n>;
```

The value prototype determines what data type can be written to the array. The two related functions must share the same name, but the value prototype and return type can be different.

Procedure calls

A procedure call has the form:

```
<procedure_name>(<arguments>);
```

Return statements

A procedure return has the form:

```
return;
```

A function return has the form:

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

```
return <expression>;
```

where `<expression>` is of the type declared in the function prototype line.

K11.5.3 Conditional control structures

This section describes how conditional control structures are used in the pseudocode.

if … then … else …

In addition to being a ternary operator, a multi-line `if … then … else …` structure can act as a control structure and has the form:

```
if <boolean_expression> then
    <statement 1>;
    <statement 2>;
    …
    <statement n>;

elsif <boolean_expression> then
    <statement a>;
    <statement b>;
    …
    <statement z>;
else
    <statement A>;
    <statement B>;
    …
    <statement Z>;
```

The block of lines consisting of `elsif` and its indented statements is optional, and multiple `elsif` blocks can be used.

The block of lines consisting of `else` and its indented statements is optional.

Abbreviated one-line forms can be used when the `then` part, and in the `else` part if it is present, contain only simple statements such as:

```
if <boolean_expression> then <statement 1>;
if <boolean_expression> then <statement 1>; else <statement A>;
if <boolean_expression> then <statement 1>; <statement 2>; else <statement A>;
```

Note

In these forms, `<statement 1>`, `<statement 2>` and `<statement A>` must be terminated by semicolons. This and the fact that the `else` part is optional distinguish its use as a control structure from its use as a ternary operator.

case … of …

A `case … of …` structure has the form:

```
case <expression> of
    when <literal values1>
        <statement 1>;
        <statement 2>;
        …
        <statement n>;

    when <literal values2>
        <statement 1>;
        <statement 2>;
        …
        <statement n>;

    … more "when" groups if required …
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

```
otherwise
    <statement A>;
    <statement B>;
    …
    <statement Z>;
```

In this structure, `<literal values1>` and `<literal values2>` consist of literal values of the same type as `<expression>`, separated by commas. There can be additional `when` groups in the structure. Abbreviated one line forms of `when` and `otherwise` parts can be used when they contain only simple statements.

If `<expression>` has a bitstring type, the literal values can also include bitstring literals containing `'x'` bits, known as bitmasks. For details see *Equality and non-equality testing* on page K11-6028.

K11.5.4 Loop control structures

This section describes the three loop control structures used in the pseudocode.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

repeat … until …

A `repeat … until …` structure has the form:

```
repeat
    <statement 1>;
    <statement 2>;
    …
    <statement n>;
until <boolean_expression>;
```

It executes the statement block at least once, and the loop repeats until `<boolean expression>` evaluates to `TRUE`. Variables explicitly declared inside the loop body have scope local to that loop and might not be accessed outside the loop body.

while … do

A `while … do` structure has the form:

```
while <boolean_expression> do
    <statement 1>;
    <statement 2>;
    …
    <statement n>;
```

It begins executing the statement block only if the Boolean expression is true. The loop then runs until the expression is false.

for …

A `for …` structure has the form:

```
for <assignable_expression> = <integer_expr1> to <integer_expr2>
    <statement 1>;
    <statement 2>;
    …
    <statement n>;
```

The `<assignable_expression>` is initialized to `<integer_expr1>` and compared to `<integer_expr2>`. If `<integer_expr1>` is less than `<integer_expr2>`, the loop body is executed and the `<assignable_expression>` incremented by one. This repeats until `<assignable expression>` is more than or equal to `<integer_expr2>`.

There is an alternate form:

```
for <assignable_expression> = <integer_expr1> downto <integer_expr2>
```

where `<integer_expr1>` is decremented after the loop body executes and continues until `<assignable expression>` is less than or equal than `<integer_expr2>`.

K11.5.5 Special statements

This section describes statements with particular architecturally-defined behaviors.

UNDEFINED

This subsection describes the statement:

```
UNDEFINED;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that the Undefined Instruction exception is taken.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

UNPREDICTABLE

This subsection describes the statement:

```
UNPREDICTABLE;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is UNPREDICTABLE.

SEE…

This subsection describes the statement:

```
SEE <reference>;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that nothing occurs as a result of the current pseudocode because some other piece of pseudocode defines the required behavior. The `<reference>` indicates where that other pseudocode can be found.

It usually refers to another instruction, but can also refer to another encoding or note of the same instruction.

IMPLEMENTATION_DEFINED

This subsection describes the statement:

```
IMPLEMENTATION_DEFINED {"<text>"};
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is IMPLEMENTATION DEFINED. An optional `<text>` field can give more information.

K11.5.6 Comments

The pseudocode supports two styles of comments:

- `//` starts a comment that is terminated by the end of the line.
- `/*` starts a comment that is terminated by `*/`.

`/**/` statements might not be nested, and the first `*/` ends the comment.

Note

Comment lines do not require a terminating semicolon.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

K11.6 Built-in functions

This section describes:

- *Bitstring manipulation functions*
- *Arithmetic functions* on page K11-6042

K11.6.1 Bitstring manipulation functions

The following bitstring manipulation functions are defined:

Bitstring length and most significant bit

If x is a bitstring:

- The bitstring length function `Len(x)` returns the length of x as an integer.

Bitstring concatenation and replication

If x is a bitstring and n is an integer with `n >= 0`:

- `Replicate(x, n)` is the bitstring of length `n*Len(x)` consisting of n copies of x concatenated together.
- `Zeros(n)` = `Replicate('0', n)`.
- `Ones(n)` = `Replicate('1', n)`.

Bitstring count

If x is a bitstring, `BitCount(x)` is an integer result equal to the number of bits of x that are ones.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Testing a bitstring for being all zero or all ones

If x is a bitstring:

- `IsZero(x)` produces `TRUE` if all of the bits of x are zeros and `FALSE` if any of them are ones
- `IsZeroBit(x)` produces `'1'` if all of the bits of x are zeros and `'0'` if any of them are ones.

`IsOnes(x)` and `IsOnesBit(x)` work in the corresponding ways. This means:

```
IsZero(x)    = (BitCount(x) == 0)
IsOnes(x)    = (BitCount(x) == Len(x))
IsZeroBit(x) = if IsZero(x) then '1' else '0'
IsOnesBit(x) = if IsOnes(x) then '1' else '0'
```

Lowest and highest set bits of a bitstring

If x is a bitstring, and `N = Len(x)`:

- `LowestSetBit(x)` is the minimum bit number of any of the bits of x that are ones. If all of its bits are zeros, `LowestSetBit(x) = N`.
- `HighestSetBit(x)` is the maximum bit number of any of the bits of x that are ones. If all of its bits are zeros, `HighestSetBit(x) = -1`.
- `CountLeadingZeroBits(x)` is the number of zero bits at the left end of x, in the range 0 to *N*. This means:

  `CountLeadingZeroBits(x) = N - 1 - HighestSetBit(x)`.
- `CountLeadingSignBits(x)` is the number of copies of the sign bit of x at the left end of x, excluding the sign bit itself, and is in the range 0 to *N*-1. This means:

  `CountLeadingSignBits(x) = CountLeadingZeroBits(x<N-1:1> EOR x<N-2:0>)`.

Zero-extension and sign-extension of bitstrings

If x is a bitstring and i is an integer, then `ZeroExtend(x, i)` is x extended to a length of i bits, by adding sufficient zero bits to its left. That is, if `i == Len(x)`, then `ZeroExtend(x, i) = x`, and if `i > Len(x)`, then:

```
ZeroExtend(x, i) = Replicate('0', i-Len(x)) : x
```

If x is a bitstring and i is an integer, then `SignExtend(x, i)` is x extended to a length of i bits, by adding sufficient copies of its leftmost bit to its left. That is, if `i == Len(x)`, then `SignExtend(x, i) = x`, and if `i > Len(x)`, then:

```
SignExtend(x, i) = Replicate(TopBit(x), i-Len(x)) : x
```

It is a pseudocode error to use either `ZeroExtend(x, i)` or `SignExtend(x, i)` in a context where it is possible that `i < Len(x)`.

Converting bitstrings to integers

If x is a bitstring, `SInt()` is the integer whose two's complement representation is x.

`UInt()` is the integer whose unsigned representation is x.

`Int(x, unsigned)` returns either `SInt(x)` or `UInt(x)` depending on the value of its second argument.

K11.6.2 Arithmetic functions

This section defines built-in arithmetic functions.

Absolute value

If x is either of type real or integer, `Abs(x)` returns the absolute value of x. The result is the same type as x.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Rounding and aligning

If x is a real:

- `RoundDown(x)` produces the largest integer `n` such that `n <= x`.
- `RoundUp(x)` produces the smallest integer `n` such that `n >= x`.
- `RoundTowardsZero(x)` produces:
  - `RoundDown(x)` if `x > 0.0`.
  - `0` if `x == 0.0`.
  - `RoundUp(x)` if `x < 0.0`.

If x and y are both of type `integer`, `Align(x, y) = y * (x DIV y)`, and is of type `integer`.

If x is of type `bitstring` and y is of type `integer`, `Align(x, y) = (Align(UInt(x), y))<Len(x)-1:0>`, and is a `bitstring` of the same length as x.

It is a pseudocode error to use either form of `Align(x, y)` in any context where y can be 0. In practice, `Align(x, y)` is only used with y a constant power of two, and the bitstring form used with `y = 2^n` has the effect of producing its argument with its n low-order bits forced to zero.

Maximum and minimum

If x and y are integers or reals, then `Max(x, y)` and `Min(x, y)` are their maximum and minimum respectively. x and y must both be of type integer or of type real. The function returns a value of the same type as its operands.

K11.7 Miscellaneous helper procedures and functions

This section lists the prototypes of miscellaneous *helper* procedures and functions used by the pseudocode, together with a brief description of the effect of the procedure or function. The pseudocode does not define the operation of these helper procedures and functions.

Note

Chapter J1 *ARMv8 Pseudocode* also has an entry for each of these functions, but currently these entries do not say anything about the effect of the function. When this information is added in Chapter J1 this section will be removed from the manual.

K11.7.1 EndOfInstruction()

This procedure terminates processing of the current instruction.

```
EndOfInstruction();
```

K11.7.2 Hint_Debug()

This procedure supplies a hint to the debug system.

```
Hint_Debug(bits(4) option);
```

K11.7.3 Hint_PreloadData()

This procedure performs a *preload data* hint.

```
Hint_PreloadData(bits(32) address);
```

K11.7.4 Hint_PreloadDataForWrite()

This procedure performs a *preload data* hint with a probability that the use will be for a write.

```
Hint_PreloadDataForWrite(bits(32) address);
```

K11.7.5 Hint_PreloadInstr()

This procedure performs a *preload instructions* hint.

```
Hint_PreloadInstr(bits(32) address);
```

K11.7.6 Hint_Yield()

This procedure performs a *Yield* hint.

```
Hint_Yield();
```

K11.7.7 IsExternalAbort()

This function returns `TRUE` if the abort currently being processed is an external abort and FALSE otherwise. It is used only in exception entry pseudocode.

```
boolean IsExternalAbort(Fault type)
    assert type != Fault_None;

boolean IsExternalAbort(FaultRecord fault);
```

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

K11.7.8 IsAsyncAbort()

This function returns `TRUE` if the abort currently being processed is an asynchronous abort, and `FALSE` otherwise. It is used only in exception entry pseudocode.

```
boolean IsAsyncAbort(Fault type)
    assert type != Fault_None;

boolean IsAsyncAbort(FaultRecord fault);
```

K11.7.9 LSInstructionSyndrome()

This function returns the extended syndrome information for a fault reported in the HSR.

```
bits(11) LSInstructionSyndrome();
```

K11.7.10 ProcessorID()

This function returns an integer that uniquely identifies the executing PE in the system.

```
integer ProcessorID();
```

K11.7.11 RemapRegsHaveResetValues()

This function returns `TRUE` if the remap registers PRRR and NMRR have their IMPLEMENTATION DEFINED reset values, and `FALSE` otherwise.

```
boolean RemapRegsHaveResetValues();
```

K11.7.12 ResetControlRegisters()

This function resets the System registers and memory-mapped control registers that have architecturally-defined reset values to those values. For more information about the affected registers see:

- *PE state on reset to AArch64 state*.
- *PE state on reset into AArch32 state*.

```
AArch64.ResetControlRegisters(boolean ResetIsCold)
AArch32.ResetControlRegisters(boolean ResetIsCold)
```

K11.7.13 ThisInstr()

This function returns the bitstring encoding of the currently-executing instruction.

```
bits(32) ThisInstr();
```

Note

Currently, this function is used only on 32-bit instruction encodings.

K11.7.14 ThisInstrLength()

This function returns the length, in bits, of the current instruction. This means it returns 32 or 16:

```
integer ThisInstrLength();
```

K11.8 ARM pseudocode definition index

This section contains the following tables:

- Table K11-3 which contains the pseudocode data types.
- Table K11-4 which contains the pseudocode operators.
- Table K11-5 on page K11-5540 which contains the pseudocode keywords and control structures.
- Table K11-6 on page K11-5541 which contains the statements with special behaviors.

Table K11-3 Index of pseudocode data types

Keyword	Meaning
`array`	Type name for the array type
`bit`	Keyword equivalent to `bits(1)`
`bits(N)`	Type name for the bitstring of length `N` data type
`boolean`	Type name for the Boolean data type
`enumeration`	Keyword to define a new enumeration type
`integer`	Type name for the integer data type
`real`	Type name for the real data type
`type`	Keyword to define a new structure

Table K11-4 Index of pseudocode operators

Operator	Meaning
`-`	Unary minus on integers or reals
	Subtraction of integers, reals and bitstrings
	Used in the left-hand side of an assignment or a tuple to discard the result
`+`	Unary plus on integers or reals
	Addition of integers, reals and bitstrings
`.`	Extract named member from a list
	Extract named bit or field from a register
`:`	Bitstring concatenation
	Integer range in bitstring extraction operator
`!`	Boolean NOT
`!=`	Comparison for inequality
`(…)`	Around arguments of procedure or function
`[…]`	Around array index
	Around arguments of array-like function
`*`	Multiplication of integers, reals, and bitstrings
`/`	Division of reals

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Table K11-4 Index of pseudocode operators (continued)

Operator	Meaning
`&&`	Boolean AND
`<`	*Less than* comparison of integers and reals
`<…>`	Slicing of specified bits of bitstring or integer
`<<`	Multiply integer by power of 2
`<=`	*Less than or equal* comparison of integers and reals
`=`	Assignment operator
`==`	Comparison for equality
`>`	*Greater than* comparison of integers and reals
`>=`	*Greater than or equal* comparison of integers and reals
`>>`	Divide integer by power of 2
`||`	Boolean OR
`^`	Exponential operator
`AND`	Bitwise AND of bitstrings
`DIV`	Quotient from integer division
`EOR`	Bitwise EOR of bitstrings
`IN`	Tests membership of a certain expression in a set of values
`MOD`	Remainder from integer division
`NOT`	Bitwise inversion of bitstrings
`OR`	Bitwise OR of bitstrings

Table K11-5 Index of pseudocode keywords and control structures

Operator	Meaning
`/*…*/`	Comment delimiters
`//`	Introduces comment terminated by end of line
`case … of …`	Control structure for the
`FALSE`	One of two values a Boolean can take (other than `TRUE`)
`for … = …to …`	Loop control structure, counting up from the initial value to the upper limit
`for … = … downto …`	Loop control structure, counting down from the initial value to the lower limit
`if … then … else …`	Condition expression selecting between two values
`if … then … else …`	Conditional control structure
`otherwise`	Introduces default case in `case … of …` control structure

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Table K11-5 Index of pseudocode keywords and control structures (continued)

Operator	Meaning
`repeat … until …`	Loop control structure that runs at least once until the termination condition is satisfied
`return`	Procedure or function return
`TRUE`	One of two values a Boolean can take (other than `FALSE`)
`when`	Introduces specific case in `case … of …` control structure
`while … do …`	Loop control structure that runs until the termination condition is satisfied

Table K11-6 Index of special statements

Keyword	Meaning
`IMPLEMENTATION_DEFINED`	Describes IMPLEMENTATION DEFINED behavior
`SEE`	Points to other pseudocode to use instead
`UNDEFINED`	Cause Undefined Instruction exception
`UNKNOWN`	Unspecified value
`UNPREDICTABLE`	Unspecified behavior

Appendix K12
Pseudocode Index

This appendix provides indexes to pseudocode definitions and to the pseudocode functions. It contains the following sections:

- *Pseudocode operators and keywords* on page K12-5544.
- *Pseudocode index* on page K12-5545.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

K12.1 Pseudocode operators and keywords

See *ARM pseudocode definition index* on page K11-5539 for a full list of operators, keywords, data types, and control structures.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

K12.2 Pseudocode index

Table K12-1 indexes the definitions of the pseudocode functions.

Appendix K13
Registers Index

This appendix provides indexes to the register descriptions in this manual. It contains the following sections:

- *Introduction and register disambiguation* on page K13-5568.
- *Alphabetical index of AArch64 registers and system instructions* on page K13-5573.
- *Functional index of AArch64 registers and system instructions* on page K13-5581.
- *Alphabetical index of AArch32 registers and system instructions* on page K13-5591.
- *Functional index of AArch32 registers and system instructions* on page K13-5599.
- *Alphabetical index of memory-mapped registers* on page K13-5609.
- *Functional index of memory-mapped registers* on page K13-5614.

K13.1 Introduction and register disambiguation

In some sections of this manual, registers are referred to by a *general name*, where the description applies to more than one context. Generally, this is one of the following:

- The description applies to both AArch32 state and AArch64 state, and therefore the register names could apply to either AArch32 System registers or AArch64 System registers.
- The description applies to multiple Exception levels, and therefore at a particular Exception level the register names need to take the appropriate Exception. level suffix, _EL0, _EL1, _EL2, or _EL3.

The following sections disambiguate the general register names:

- *Register name disambiguation by Execution state*.
- *Register name disambiguation by Exception level* on page K13-5571.

K13.1.1 Register name disambiguation by Execution state

Table K13-1 disambiguates the general names of the registers by Execution state.

Table K13-1 Disambiguation of general names of registers by Execution state

General name	Short description	AArch64 register	AArch32 register
CONTEXTIDR	Context ID	CONTEXTIDR_EL1	CONTEXTIDR
DBGBCR	Debug Breakpoint Control Registers	DBGBCR<n>_EL1	DBGBCR<n>
DBGBVR	Debug Breakpoint Value Registers	DBGBVR<n>_EL1	DBGBVR<n> DBGBXVR<n>
DBGCLAIMCLR	Debug CLAIM Tag Clear register	DBGCLAIMCLR_EL1	DBGCLAIMCLR
DBGCLAIMSET	Debug CLAIM Tag Set register	DBGCLAIMSET_EL1	DBGCLAIMSET
DBGDTRRX	Debug Data Transfer Register, Receive	DBGDTRRX_EL0	DBGDTRRXint
DBGDTRTX	Debug Data Transfer Register, Transmit	DBGDTRTX_EL0	DBGDTRTXint
DBGPRCR	Debug Power Control Register	DBGPRCR_EL1	DBGPRCR
DBGVCR	Debug Vector Catch Register	DBGVCR32_EL2	DBGVCR
DBGWCR	Debug Watchpoint Control Registers	DBGWCR<n>_EL1	DBGWCR<n>
DBGWVR	Debug Watchpoint Value Registers	DBGWVR<n>_EL1	DBGWVR<n>
DCCINT	Debug Comms Channel Interrupt Enable Register	MDCCINT_EL1	DBGDCCINT
DCCSR	Debug Comms Channel Status Register	MDCCSR_EL0	DBGDSCRint
DBGAUTHSTATUS	Debug Authentication Status	DBGAUTHSTATUS_EL1	DBGAUTHSTATUS
DLR	Debug Link Register	DLR_EL0[31:0]	DLR
DSCR	Debug System Control Register	MDSCR_EL1	DBGDSCRext
DSPSR	Debug Saved PE State Register	DSPSR_EL0	DSPSR
FAR	Fault Address Register	FAR_EL1 FAR_EL2 FAR_EL3 HPFAR_EL2	DFAR, IFAR HDFAR, HIFAR FAR_EL3 HPFAR

Table K13-1 Disambiguation of general names of registers by Execution state (continued)

General name	Short description	AArch64 register	AArch32 register
HCR	Hypervisor Configuration Register	HCR_EL2	HCR HCR2
HDCR	Hyp or EL2 Debug Control Register	MDCR_EL2	HDCR
HSCTLR	Hypervisor System Control Register	SCTLR_EL2	HSCTLR
HTTBR	EL2 Translation Table Base Register	TTBR0_EL2	HTTBR
ISR	Interrupt Status Register	ISR_EL1	ISR
MPIDR	Multiprocessor Affinity Register	MPIDR_EL1	MPIDR
OSDLR	OS Double-Lock Register	OSDLR_EL1	DBGOSDLR
OSDTRRX	OS Lock Data Transfer Register, Receive	OSDTRRX_EL1	DBGDTRRXext
OSDTRTX	OS Lock Data Transfer Register, Transmit	OSDTRTX_EL1	DBGDTRTXext
OSECCR	OS Lock Exception Catch Control Register	OSECCR_EL1	DBGOSECCR
OSLAR	OS Lock Access Register	OSLAR_EL1	DBGOSLAR
OSLSR	OS Lock Status Register	OSLSR_EL1	DBGOSLSR
SCR	Secure Configuration Register	SCR_EL3	SCR
SCTLR	System Control Register	SCTLR_EL1 SCTLR_EL2 SCTLR_EL3	SCTLR (NS) HSCTLR SCTLR (S)
SDCR	Secure or EL3 Debug Configuration Register	MDCR_EL3	SDCR
SDER	Secure Debug Enable Register	SDER32_EL3	SDER
SPSR	Saved Program Status Register	SPSR_EL1 SPSR_EL2 SPSR_EL3	SPSR (general description) SPSR_abt SPSR_fiq SPSR_hyp SPSR_irq SPSR_mon SPSR_svc SPSR_und
TCR	Translation Control Register	TCR_EL1 TCR_EL2 TCR_EL3 VTCR_EL2	TTBCR(NS) HTCR TTBCR(S) VTCR
TTBR	Translation Table Base Register	TTBR0_EL1 TTBR0_EL2 TTBR0_EL3 TTBR1_EL1 VTTBR_EL2	TTBR0 TTBR1 HTTBR VTTBR

Table K13-1 Disambiguation of general names of registers by Execution state (continued)

General name	Short description	AArch64 register	AArch32 register
VCR	PL1&0 stage 2 Translation Control Register	VTCR_EL2	VTCR
VBAR	Vector Base Address Register	VBAR_EL1 VBAR_EL2 VBAR_EL3	VBAR HVBAR MVBAR
VTTBR	PL1&0 stage 2 Translation Table Base Register	VTTBR_EL2	VTTBR

Table K13-2 disambiguates the general names of the System registers that provide access to the Performance Monitors by Execution state.

Table K13-2 Disambiguation of general names of the Performance Monitors System registers by Execution state

General name	Short description	AArch64 register	AArch32 register
PMCCFILTR	Cycle Count Filter Register	PMCCFILTR_EL0	PMCCFILTR
PMCCNTR	Cycle Count Register	PMCCNTR_EL0	PMCCNTR
PMCEID0	Performance Monitors Cycle Count Filter Register 0	PMCEID0_EL0	PMCEID0
PMCEID1	Performance Monitors Cycle Count Filter Register 1	PMCEID1_EL0	PMCEID1
PMCNTENCLR	Performance Monitors Count Enable Clear register	PMCNTENCLR_EL0	PMINTENCLR
PMCNTENSET	Performance Monitors Count Enable Set register	PMCNTENSET_EL0	PMCNTENSET
PMCR	Performance Monitors Control Register	PMCR_EL0	PMCR
PMEVCNTR<n>	Performance Monitors Event Count Registers, n = 0-30	PMEVCNTR<n>_EL0	PMEVCNTR<n>
PMEVTYPER<n>	Performance Monitors Event Type Registers, n = 0-30	PMEVTYPER<n>_EL0	PMEVTYPER<n>
PMINTENCLR	Performance Monitors Interrupt Enable Clear register	PMINTENCLR_EL1	PMINTENCLR
PMINTENSET	Performance Monitors Interrupt Enable Set register	PMINTENSET_EL1	PMINTENSET
PMOVSCLR	Performance Monitors Overflow Flag Status Register	PMOVSCLR_EL0	PMOVSR
PMOVSSET	Performance Monitors Overflow Flag Status Set register	PMOVSSET_EL0	PMOVSSET
PMSELR	Performance Monitors Event Counter Selection Register	PMSELR_EL0	PMSELR
PMSWINC	Performance Monitors Software Increment register	PMSWINC_EL0	PMSWINC
PMUSERENR	Performance Monitors User Enable Register	PMUSERENR_EL0	PMUSERENR
PMXEVCNTR	Performance Monitors Selected Event Count Register	PMXEVCNTR_EL0	PMXEVCNTR
PMXEVTYPER	Performance Monitors Selected Event Type Register	PMXEVTYPER_EL0	PMXEVTYPER

Table K13-3 disambiguates the general names of the System registers that provide access to the Performance Monitors by Execution state.

Table K13-3 Disambiguation of general names of the Generic Timer System registers by Execution state

General name	Short description	AArch64 register	AArch32 register
CNTFRQ	Counter-timer Frequency register	CNTFRQ_EL0	CNTFRQ
CNTHCTL	Counter-timer Hypervisor Control register	CNTHCTL_EL2	CNTHCTL
CNTHP_CTL	Counter-timer Hypervisor Physical Timer Control register	CNTHP_CTL_EL2	CNTHP_CTL
CNTHP_CVAL	Counter-timer Hypervisor Physical Timer CompareValue register	CNTHP_CVAL_EL2	CNTHP_CVAL
CNTHP_TVAL	Counter-timer Hypervisor Physical Timer TimerValue register	CNTHP_TVAL_EL2	CNTHP_TVAL
CNTKCTL	Counter-timer Kernel Control register	CNTKCTL_EL1	CNTKCTL
CNTP_CTL	Counter-timer Physical Timer Control register	CNTP_CTL_EL0	CNTP_CTL
CNTP_CVAL	Counter-timer Physical Timer CompareValue register	CNTP_CVAL_EL0	CNTP_CVAL
CNTP_TVAL	Counter-timer Physical Timer TimerValue register	CNTP_TVAL_EL0	CNTP_TVAL
CNTPCT	Counter-timer Physical Count register	CNTPCT_EL0	CNTPCT
CNTPS_CTL	Counter-timer Physical Secure Timer Control register	CNTPS_CTL_EL1	-
CNTPS_CVAL	Counter-timer Physical Secure Timer CompareValue register	CNTPS_CVAL_EL1	-
CNTPS_TVAL	Counter-timer Physical Secure Timer TimerValue register	CNTPS_TVAL_EL1	-
CNTV_CTL	Counter-timer Virtual Timer Control register	CNTV_CTL_EL0	CNTV_CTL
CNTV_CVAL	Counter-timer Virtual Timer CompareValue register	CNTV_CVAL_EL0	CNTV_CVAL
CNTV_TVAL	Counter-timer Virtual Timer TimerValue register	CNTV_TVAL_EL0	CNTV_TVAL
CNTVCT	Counter-timer Virtual Count register	CNTVCT_EL0	CNTVCT
CNTVOFF	Counter-timer Virtual Offset register	CNTVOFF_EL2	CNTVOFF

K13.1.2 Register name disambiguation by Exception level

Table K13-4 disambiguates the general names of the AArch64 System registers by Exception level.

Table K13-4 Disambiguation of AArch64 System registers by Exception level

General form	EL0	EL1	EL2	EL3
AFSR0_ELx	-	AFSR0_EL1	AFSR0_EL2	AFSR0_EL3
AFSR1_ELx	-	AFSR1_EL1	AFSR1_EL2	AFSR1_EL3
CPTR_ELx	-	-	CPTR_EL2	CPTR_EL3
ELR_ELx	-	ELR_EL1	ELR_EL2	ELR_EL3
ESR_ELx	-	ESR_EL1	ESR_EL2	ESR_EL3
FAR_ELx	-	FAR_EL1	FAR_EL2	FAR_EL3

K13.2 Alphabetical index of AArch64 registers and system instructions

This section is an index of AArch64 registers and system instructions in alphabetical order.

Table K13-5 Alphabetical index of AArch64 Registers

Register	Description, see
ACTLR_EL1	*ACTLR_EL1, Auxiliary Control Register (EL1)* on page D7-1810
ACTLR_EL2	*ACTLR_EL2, Auxiliary Control Register (EL2)* on page D7-1811
ACTLR_EL3	*ACTLR_EL3, Auxiliary Control Register (EL3)* on page D7-1812
AFSR0_EL1	*AFSR0_EL1, Auxiliary Fault Status Register 0 (EL1)* on page D7-1813
AFSR0_EL2	*AFSR0_EL2, Auxiliary Fault Status Register 0 (EL2)* on page D7-1814
AFSR0_EL3	*AFSR0_EL3, Auxiliary Fault Status Register 0 (EL3)* on page D7-1815
AFSR1_EL1	*AFSR1_EL1, Auxiliary Fault Status Register 1 (EL1)* on page D7-1816
AFSR1_EL2	*AFSR1_EL2, Auxiliary Fault Status Register 1 (EL2)* on page D7-1817
AFSR1_EL3	*AFSR1_EL3, Auxiliary Fault Status Register 1 (EL3)* on page D7-1818
AIDR_EL1	*AIDR_EL1, Auxiliary ID Register* on page D7-1819
AMAIR_EL1	*AMAIR_EL1, Auxiliary Memory Attribute Indirection Register (EL1)* on page D7-1820
AMAIR_EL2	*AMAIR_EL2, Auxiliary Memory Attribute Indirection Register (EL2)* on page D7-1822
AMAIR_EL3	*AMAIR_EL3, Auxiliary Memory Attribute Indirection Register (EL3)* on page D7-1823
AT S12E0R	*AT S12E0R, Address Translate Stages 1 and 2 EL0 Read* on page C5-358
AT S12E0W	*AT S12E0W, Address Translate Stages 1 and 2 EL0 Write* on page C5-359
AT S12E1R	*AT S12E1R, Address Translate Stages 1 and 2 EL1 Read* on page C5-360
AT S12E1W	*AT S12E1W, Address Translate Stages 1 and 2 EL1 Write* on page C5-361
AT S1E0R	*AT S1E0R, Address Translate Stage 1 EL0 Read* on page C5-362
AT S1E0W	*AT S1E0W, Address Translate Stage 1 EL0 Write* on page C5-363
AT S1E1R	*AT S1E1R, Address Translate Stage 1 EL1 Read* on page C5-364
AT S1E1W	*AT S1E1W, Address Translate Stage 1 EL1 Write* on page C5-365
AT S1E2R	*AT S1E2R, Address Translate Stage 1 EL2 Read* on page C5-366
AT S1E2W	*AT S1E2W, Address Translate Stage 1 EL2 Write* on page C5-367
AT S1E3R	*AT S1E3R, Address Translate Stage 1 EL3 Read* on page C5-368
AT S1E3W	*AT S1E3W, Address Translate Stage 1 EL3 Write* on page C5-369
CCSIDR_EL1	*CCSIDR_EL1, Current Cache Size ID Register* on page D7-1824
CLIDR_EL1	*CLIDR_EL1, Cache Level ID Register* on page D7-1826
CNTFRQ_EL0	*CNTFRQ_EL0, Counter-timer Frequency register* on page D7-2173
CNTHCTL_EL2	*CNTHCTL_EL2, Counter-timer Hypervisor Control register* on page D7-2175
CNTHP_CTL_EL2	*CNTHP_CTL_EL2, Counter-timer Hypervisor Physical Timer Control register* on page D7-2177

K13.3 Functional index of AArch64 registers and system instructions

This section is an index of the AArch64 registers and system instructions, divided by functional group.

K13.3.1 Special-purpose registers

This section is an index to the registers in the Special-purpose registers functional group.

Table K13-6 Special-purpose registers

Register	Description, see
DLR_EL0	*DLR_EL0, Debug Link Register* on page D7-2094
DSPSR_EL0	*DSPSR_EL0, Debug Saved Program Status Register* on page D7-2095
ELR_EL1	*ELR_EL1, Exception Link Register (EL1)* on page C5-294
ELR_EL2	*ELR_EL2, Exception Link Register (EL2)* on page C5-295
ELR_EL3	*ELR_EL3, Exception Link Register (EL3)* on page C5-296
FPCR	*FPCR, Floating-point Control Register* on page C5-297
FPSR	*FPSR, Floating-point Status Register* on page C5-301
SP_EL0	*SP_EL0, Stack Pointer (EL0)* on page C5-306
SP_EL1	*SP_EL1, Stack Pointer (EL1)* on page C5-307
SP_EL2	*SP_EL2, Stack Pointer (EL2)* on page C5-309
SP_EL3	*SP_EL3, Stack Pointer (EL3)* on page C5-311
SPSR_abt	*SPSR_abt, Saved Program Status Register (Abort mode)* on page C5-313
SPSR_EL1	*SPSR_EL1, Saved Program Status Register (EL1)* on page C5-316
SPSR_EL2	*SPSR_EL2, Saved Program Status Register (EL2)* on page C5-321
SPSR_EL3	*SPSR_EL3, Saved Program Status Register (EL3)* on page C5-326
SPSR_fiq	*SPSR_fiq, Saved Program Status Register (FIQ mode)* on page C5-331
SPSR_irq	*SPSR_irq, Saved Program Status Register (IRQ mode)* on page C5-334
SPSR_und	*SPSR_und, Saved Program Status Register (Undefined mode)* on page C5-337

K13.3.2 VMSA-specific registers

This section is an index to the registers in the Virtual memory control registers functional group.

Table K13-7 VMSA-specific registers

Register	Description, see
AMAIR_EL1	*AMAIR_EL1, Auxiliary Memory Attribute Indirection Register (EL1)* on page D7-1820
AMAIR_EL2	*AMAIR_EL2, Auxiliary Memory Attribute Indirection Register (EL2)* on page D7-1822
AMAIR_EL3	*AMAIR_EL3, Auxiliary Memory Attribute Indirection Register (EL3)* on page D7-1823
CONTEXTIDR_EL1	*CONTEXTIDR_EL1, Context ID Register (EL1)* on page D7-1828
DACR32_EL2	*DACR32_EL2, Domain Access Control Register* on page D7-1840

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Table K13-7 VMSA-specific registers (continued)

Register	Description, see
MAIR_EL1	*MAIR_EL1, Memory Attribute Indirection Register (EL1)* on page D7-1972
MAIR_EL2	*MAIR_EL2, Memory Attribute Indirection Register (EL2)* on page D7-1975
MAIR_EL3	*MAIR_EL3, Memory Attribute Indirection Register (EL3)* on page D7-1977
TCR_EL1	*TCR_EL1, Translation Control Register (EL1)* on page D7-2024
TCR_EL2	*TCR_EL2, Translation Control Register (EL2)* on page D7-2029
TCR_EL3	*TCR_EL3, Translation Control Register (EL3)* on page D7-2032
TTBR0_EL1	*TTBR0_EL1, Translation Table Base Register 0 (EL1)* on page D7-2040
TTBR0_EL2	*TTBR0_EL2, Translation Table Base Register 0 (EL2)* on page D7-2042
TTBR0_EL3	*TTBR0_EL3, Translation Table Base Register 0 (EL3)* on page D7-2044
TTBR1_EL1	*TTBR1_EL1, Translation Table Base Register 1 (EL1)* on page D7-2046
VTCR_EL2	*VTCR_EL2, Virtualization Translation Control Register* on page D7-2057
VTTBR_EL2	*VTTBR_EL2, Virtualization Translation Table Base Register* on page D7-2060

K13.3.3 ID registers

This section is an index to the registers in the Identification registers functional group.

Table K13-8 ID registers

Register	Description, see
AIDR_EL1	*AIDR_EL1, Auxiliary ID Register* on page D7-1819
CCSIDR_EL1	*CCSIDR_EL1, Current Cache Size ID Register* on page D7-1824
CLIDR_EL1	*CLIDR_EL1, Cache Level ID Register* on page D7-1826
CSSELR_EL1	*CSSELR_EL1, Cache Size Selection Register* on page D7-1836
CTR_EL0	*CTR_EL0, Cache Type Register* on page D7-1838
DCZID_EL0	*DCZID_EL0, Data Cache Zero ID register* on page D7-1842
ID_AA64AFR0_EL1	*ID_AA64AFR0_EL1, AArch64 Auxiliary Feature Register 0* on page D7-1908
ID_AA64AFR1_EL1	*ID_AA64AFR1_EL1, AArch64 Auxiliary Feature Register 1* on page D7-1910
ID_AA64DFR0_EL1	*ID_AA64DFR0_EL1, AArch64 Debug Feature Register 0* on page D7-1911
ID_AA64DFR1_EL1	*ID_AA64DFR1_EL1, AArch64 Debug Feature Register 1* on page D7-1913
ID_AA64ISAR0_EL1	*ID_AA64ISAR0_EL1, AArch64 Instruction Set Attribute Register 0* on page D7-1914
ID_AA64ISAR1_EL1	*ID_AA64ISAR1_EL1, AArch64 Instruction Set Attribute Register 1* on page D7-1916
ID_AA64MMFR0_EL1	*ID_AA64MMFR0_EL1, AArch64 Memory Model Feature Register 0* on page D7-1917
ID_AA64MMFR1_EL1	*ID_AA64MMFR1_EL1, AArch64 Memory Model Feature Register 1* on page D7-1920
ID_AA64PFR0_EL1	*ID_AA64PFR0_EL1, AArch64 Processor Feature Register 0* on page D7-1921

Non-Confidential - Beta

Table K13-8 ID registers (continued)

Register	Description, see
ID_AA64PFR1_EL1	*ID_AA64PFR1_EL1, AArch64 Processor Feature Register 1* on page D7-1923
ID_AFR0_EL1	*ID_AFR0_EL1, AArch32 Auxiliary Feature Register 0* on page D7-1924
ID_DFR0_EL1	*ID_DFR0_EL1, AArch32 Debug Feature Register 0* on page D7-1926
ID_ISAR0_EL1	*ID_ISAR0_EL1, AArch32 Instruction Set Attribute Register 0* on page D7-1929
ID_ISAR1_EL1	*ID_ISAR1_EL1, AArch32 Instruction Set Attribute Register 1* on page D7-1932
ID_ISAR2_EL1	*ID_ISAR2_EL1, AArch32 Instruction Set Attribute Register 2* on page D7-1935
ID_ISAR3_EL1	*ID_ISAR3_EL1, AArch32 Instruction Set Attribute Register 3* on page D7-1938
ID_ISAR4_EL1	*ID_ISAR4_EL1, AArch32 Instruction Set Attribute Register 4* on page D7-1941
ID_ISAR5_EL1	*ID_ISAR5_EL1, AArch32 Instruction Set Attribute Register 5* on page D7-1944
ID_MMFR0_EL1	*ID_MMFR0_EL1, AArch32 Memory Model Feature Register 0* on page D7-1946
ID_MMFR1_EL1	*ID_MMFR1_EL1, AArch32 Memory Model Feature Register 1* on page D7-1949
ID_MMFR2_EL1	*ID_MMFR2_EL1, AArch32 Memory Model Feature Register 2* on page D7-1953
ID_MMFR3_EL1	*ID_MMFR3_EL1, AArch32 Memory Model Feature Register 3* on page D7-1956
ID_MMFR4_EL1	*ID_MMFR4_EL1, AArch32 Memory Model Feature Register 4* on page D7-1959
ID_PFR0_EL1	*ID_PFR0_EL1, AArch32 Processor Feature Register 0* on page D7-1961
ID_PFR1_EL1	*ID_PFR1_EL1, AArch32 Processor Feature Register 1* on page D7-1963
MIDR_EL1	*MIDR_EL1, Main ID Register* on page D7-1979
MPIDR_EL1	*MPIDR_EL1, Multiprocessor Affinity Register* on page D7-1981
MVFR0_EL1	*MVFR0_EL1, AArch32 Media and VFP Feature Register 0* on page D7-1983
MVFR1_EL1	*MVFR1_EL1, AArch32 Media and VFP Feature Register 1* on page D7-1986
MVFR2_EL1	*MVFR2_EL1, AArch32 Media and VFP Feature Register 2* on page D7-1989
REVIDR_EL1	*REVIDR_EL1, Revision ID Register* on page D7-1994
VMPIDR_EL2	*VMPIDR_EL2, Virtualization Multiprocessor ID Register* on page D7-2053
VPIDR_EL2	*VPIDR_EL2, Virtualization Processor ID Register* on page D7-2055

K13.3.4 Performance monitors registers

This section is an index to the registers in the Performance Monitors registers functional group.

Table K13-9 Performance monitors registers

Register	Description, see
PMCCFILTR_EL0	*PMCCFILTR_EL0, Performance Monitors Cycle Count Filter Register* on page D7-2133
PMCCNTR_EL0	*PMCCNTR_EL0, Performance Monitors Cycle Count Register* on page D7-2135
PMCEID0_EL0	*PMCEID0_EL0, Performance Monitors Common Event Identification register 0* on page D7-2137

Table K13-9 Performance monitors registers (continued)

Register	Description, see
PMCEID1_EL0	*PMCEID1_EL0, Performance Monitors Common Event Identification register 1* on page D7-2139
PMCNTENCLR_EL0	*PMCNTENCLR_EL0, Performance Monitors Count Enable Clear register* on page D7-2141
PMCNTENSET_EL0	*PMCNTENSET_EL0, Performance Monitors Count Enable Set register* on page D7-2143
PMCR_EL0	*PMCR_EL0, Performance Monitors Control Register* on page D7-2145
PMEVCNTR<n>_EL0	*PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30* on page D7-2149
PMEVTYPER<n>_EL0	*PMEVTYPER<n>_EL0, Performance Monitors Event Type Registers, n = 0 - 30* on page D7-2151
PMINTENCLR_EL1	*PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear register* on page D7-2154
PMINTENSET_EL1	*PMINTENSET_EL1, Performance Monitors Interrupt Enable Set register* on page D7-2156
PMOVSCLR_EL0	*PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear Register* on page D7-2158
PMOVSSET_EL0	*PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set register* on page D7-2160
PMSELR_EL0	*PMSELR_EL0, Performance Monitors Event Counter Selection Register* on page D7-2162
PMSWINC_EL0	*PMSWINC_EL0, Performance Monitors Software Increment register* on page D7-2164
PMUSERENR_EL0	*PMUSERENR_EL0, Performance Monitors User Enable Register* on page D7-2166
PMXEVCNTR_EL0	*PMXEVCNTR_EL0, Performance Monitors Selected Event Count Register* on page D7-2168
PMXEVTYPER_EL0	*PMXEVTYPER_EL0, Performance Monitors Selected Event Type Register* on page D7-2170

K13.3.5 Debug registers

This section is an index to the registers in the Debug registers functional group.

Table K13-10 Debug registers

Register	Description, see
DBGAUTHSTATUS_EL1	*DBGAUTHSTATUS_EL1, Debug Authentication Status register* on page D7-2063
DBGBCR<n>_EL1	*DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 15* on page D7-2065
DBGBVR<n>_EL1	*DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 15* on page D7-2069
DBGCLAIMCLR_EL1	*DBGCLAIMCLR_EL1, Debug Claim Tag Clear register* on page D7-2072
DBGCLAIMSET_EL1	*DBGCLAIMSET_EL1, Debug Claim Tag Set register* on page D7-2074
DBGDTR_EL0	*DBGDTR_EL0, Debug Data Transfer Register, half-duplex* on page D7-2076
DBGDTRRX_EL0	*DBGDTRRX_EL0, Debug Data Transfer Register, Receive* on page D7-2078
DBGDTRTX_EL0	*DBGDTRTX_EL0, Debug Data Transfer Register, Transmit* on page D7-2080
DBGPRCR_EL1	*DBGPRCR_EL1, Debug Power Control Register* on page D7-2082
DBGVCR32_EL2	*DBGVCR32_EL2, Debug Vector Catch Register* on page D7-2084

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Table K13-10 Debug registers (continued)

Register	Description, see
DBGWCR<n>_EL1	*DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15* on page D7-2088
DBGWVR<n>_EL1	*DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 15* on page D7-2092
DLR_EL0	*DLR_EL0, Debug Link Register* on page D7-2094
DSPSR_EL0	*DSPSR_EL0, Debug Saved Program Status Register* on page D7-2095
MDCCINT_EL1	*MDCCINT_EL1, Monitor DCC Interrupt Enable Register* on page D7-2100
MDCCSR_EL0	*MDCCSR_EL0, Monitor DCC Status Register* on page D7-2102
MDCR_EL2	*MDCR_EL2, Monitor Debug Configuration Register (EL2)* on page D7-2104
MDCR_EL3	*MDCR_EL3, Monitor Debug Configuration Register (EL3)* on page D7-2108
MDRAR_EL1	*MDRAR_EL1, Monitor Debug ROM Address Register* on page D7-2112
MDSCR_EL1	*MDSCR_EL1, Monitor Debug System Control Register* on page D7-2114
OSDLR_EL1	*OSDLR_EL1, OS Double Lock Register* on page D7-2118
OSDTRRX_EL1	*OSDTRRX_EL1, OS Lock Data Transfer Register, Receive* on page D7-2120
OSDTRTX_EL1	*OSDTRTX_EL1, OS Lock Data Transfer Register, Transmit* on page D7-2122
OSECCR_EL1	*OSECCR_EL1, OS Lock Exception Catch Control Register* on page D7-2124
OSLAR_EL1	*OSLAR_EL1, OS Lock Access Register* on page D7-2126
OSLSR_EL1	*OSLSR_EL1, OS Lock Status Register* on page D7-2128
SDER32_EL3	*SDER32_EL3, AArch32 Secure Debug Enable Register* on page D7-2130

K13.3.6 Generic timer registers

This section is an index to the registers in the Generic Timer registers functional group.

Table K13-11 Generic timer registers

Register	Description, see
CNTFRQ_EL0	*CNTFRQ_EL0, Counter-timer Frequency register* on page D7-2173
CNTHCTL_EL2	*CNTHCTL_EL2, Counter-timer Hypervisor Control register* on page D7-2175
CNTHP_CTL_EL2	*CNTHP_CTL_EL2, Counter-timer Hypervisor Physical Timer Control register* on page D7-2177
CNTHP_CVAL_EL2	*CNTHP_CVAL_EL2, Counter-timer Hypervisor Physical Timer CompareValue register* on page D7-2179
CNTHP_TVAL_EL2	*CNTHP_TVAL_EL2, Counter-timer Hypervisor Physical Timer TimerValue register* on page D7-2180
CNTKCTL_EL1	*CNTKCTL_EL1, Counter-timer Kernel Control register* on page D7-2181
CNTP_CTL_EL0	*CNTP_CTL_EL0, Counter-timer Physical Timer Control register* on page D7-2184
CNTP_CVAL_EL0	*CNTP_CVAL_EL0, Counter-timer Physical Timer CompareValue register* on page D7-2186
CNTP_TVAL_EL0	*CNTP_TVAL_EL0, Counter-timer Physical Timer TimerValue register* on page D7-2187

Table K13-11 Generic timer registers (continued)

Register	Description, see
CNTPCT_EL0	*CNTPCT_EL0, Counter-timer Physical Count register* on page D7-2189
CNTPS_CTL_EL1	*CNTPS_CTL_EL1, Counter-timer Physical Secure Timer Control register* on page D7-2190
CNTPS_CVAL_EL1	*CNTPS_CVAL_EL1, Counter-timer Physical Secure Timer CompareValue register* on page D7-2192
CNTPS_TVAL_EL1	*CNTPS_TVAL_EL1, Counter-timer Physical Secure Timer TimerValue register* on page D7-2193
CNTV_CTL_EL0	*CNTV_CTL_EL0, Counter-timer Virtual Timer Control register* on page D7-2195
CNTV_CVAL_EL0	*CNTV_CVAL_EL0, Counter-timer Virtual Timer CompareValue register* on page D7-2197
CNTV_TVAL_EL0	*CNTV_TVAL_EL0, Counter-timer Virtual Timer TimerValue register* on page D7-2198
CNTVCT_EL0	*CNTVCT_EL0, Counter-timer Virtual Count register* on page D7-2200
CNTVOFF_EL2	*CNTVOFF_EL2, Counter-timer Virtual Offset register* on page D7-2201

K13.3.7 Cache maintenance system instructions

This section is an index to the registers in the Cache maintenance instructions functional group.

Table K13-12 Cache maintenance system instructions

Register	Description, see
DC CISW	*DC CISW, Data or unified Cache line Clean and Invalidate by Set/Way* on page C5-341
DC CIVAC	*DC CIVAC, Data or unified Cache line Clean and Invalidate by VA to PoC* on page C5-343
DC CSW	*DC CSW, Data or unified Cache line Clean by Set/Way* on page C5-344
DC CVAC	*DC CVAC, Data or unified Cache line Clean by VA to PoC* on page C5-346
DC CVAU	*DC CVAU, Data or unified Cache line Clean by VA to PoU* on page C5-347
DC ISW	*DC ISW, Data or unified Cache line Invalidate by Set/Way* on page C5-348
DC IVAC	*DC IVAC, Data or unified Cache line Invalidate by VA to PoC* on page C5-350
DC ZVA	*DC ZVA, Data Cache Zero by VA* on page C5-352
IC IALLU	*IC IALLU, Instruction Cache Invalidate All to PoU* on page C5-354
IC IALLUIS	*IC IALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable* on page C5-355
IC IVAU	*IC IVAU, Instruction Cache line Invalidate by VA to PoU* on page C5-356

K13.3.8 Address translation system instructions

This section is an index to the registers in the Address translation instructions functional group.

Table K13-13 Address translation system instructions

Register	Description, see
AT S12E0R	*AT S12E0R, Address Translate Stages 1 and 2 EL0 Read* on page C5-358
AT S12E0W	*AT S12E0W, Address Translate Stages 1 and 2 EL0 Write* on page C5-359
AT S12E1R	*AT S12E1R, Address Translate Stages 1 and 2 EL1 Read* on page C5-360
AT S12E1W	*AT S12E1W, Address Translate Stages 1 and 2 EL1 Write* on page C5-361
AT S1E0R	*AT S1E0R, Address Translate Stage 1 EL0 Read* on page C5-362
AT S1E0W	*AT S1E0W, Address Translate Stage 1 EL0 Write* on page C5-363
AT S1E1R	*AT S1E1R, Address Translate Stage 1 EL1 Read* on page C5-364
AT S1E1W	*AT S1E1W, Address Translate Stage 1 EL1 Write* on page C5-365
AT S1E2R	*AT S1E2R, Address Translate Stage 1 EL2 Read* on page C5-366
AT S1E2W	*AT S1E2W, Address Translate Stage 1 EL2 Write* on page C5-367
AT S1E3R	*AT S1E3R, Address Translate Stage 1 EL3 Read* on page C5-368
AT S1E3W	*AT S1E3W, Address Translate Stage 1 EL3 Write* on page C5-369

K13.3.9 TLB maintenance system instructions

This section is an index to the registers in the TLB maintenance instructions functional group.

Table K13-14 TLB maintenance system instructions

Register	Description, see
TLBI ALLE1	*TLBI ALLE1, TLB Invalidate All, EL1* on page C5-371
TLBI ALLE1IS	*TLBI ALLE1IS, TLB Invalidate All, EL1, Inner Shareable* on page C5-372
TLBI ALLE2	*TLBI ALLE2, TLB Invalidate All, EL2* on page C5-373
TLBI ALLE2IS	*TLBI ALLE2IS, TLB Invalidate All, EL2, Inner Shareable* on page C5-374
TLBI ALLE3	*TLBI ALLE3, TLB Invalidate All, EL3* on page C5-375
TLBI ALLE3IS	*TLBI ALLE3IS, TLB Invalidate All, EL3, Inner Shareable* on page C5-376
TLBI ASIDE1	*TLBI ASIDE1, TLB Invalidate by ASID, EL1* on page C5-377
TLBI ASIDE1IS	*TLBI ASIDE1IS, TLB Invalidate by ASID, EL1, Inner Shareable* on page C5-379
TLBI IPAS2E1	*TLBI IPAS2E1, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1* on page C5-381
TLBI IPAS2E1IS	*TLBI IPAS2E1IS, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1, Inner Shareable* on page C5-382
TLBI IPAS2LE1	*TLBI IPAS2LE1, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1* on page C5-384

Non-Confidential - Beta

Table K13-14 TLB maintenance system instructions (continued)

Register	Description, see
TLBI IPAS2LE1IS	*TLBI IPAS2LE1IS, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1, Inner Shareable* on page C5-385
TLBI VAAE1	*TLBI VAAE1, TLB Invalidate by VA, All ASID, EL1* on page C5-387
TLBI VAAE1IS	*TLBI VAAE1IS, TLB Invalidate by VA, All ASID, EL1, Inner Shareable* on page C5-389
TLBI VAALE1	*TLBI VAALE1, TLB Invalidate by VA, All ASID, Last level, EL1* on page C5-391
TLBI VAALE1IS	*TLBI VAALE1IS, TLB Invalidate by VA, All ASID, EL1, Inner Shareable* on page C5-393
TLBI VAE1	*TLBI VAE1, TLB Invalidate by VA, EL1* on page C5-395
TLBI VAE1IS	*TLBI VAE1IS, TLB Invalidate by VA, EL1, Inner Shareable* on page C5-397
TLBI VAE2	*TLBI VAE2, TLB Invalidate by VA, EL2* on page C5-399
TLBI VAE2IS	*TLBI VAE2IS, TLB Invalidate by VA, EL2, Inner Shareable* on page C5-401
TLBI VAE3	*TLBI VAE3, TLB Invalidate by VA, EL3* on page C5-403
TLBI VAE3IS	*TLBI VAE3IS, TLB Invalidate by VA, EL3, Inner Shareable* on page C5-405
TLBI VALE1	*TLBI VALE1, TLB Invalidate by VA, Last level, EL1* on page C5-407
TLBI VALE1IS	*TLBI VALE1IS, TLB Invalidate by VA, Last level, EL1, Inner Shareable* on page C5-409
TLBI VALE2	*TLBI VALE2, TLB Invalidate by VA, Last level, EL2* on page C5-411
TLBI VALE2IS	*TLBI VALE2IS, TLB Invalidate by VA, Last level, EL2, Inner Shareable* on page C5-413
TLBI VALE3	*TLBI VALE3, TLB Invalidate by VA, Last level, EL3* on page C5-415
TLBI VALE3IS	*TLBI VALE3IS, TLB Invalidate by VA, Last level, EL3, Inner Shareable* on page C5-417
TLBI VMALLE1	*TLBI VMALLE1, TLB Invalidate by VMID, All at stage 1, EL1* on page C5-419
TLBI VMALLE1IS	*TLBI VMALLE1IS, TLB Invalidate by VMID, All at stage 1, EL1, Inner Shareable* on page C5-420
TLBI VMALLS12E1	*TLBI VMALLS12E1, TLB Invalidate by VMID, All at Stage 1 and 2, EL1* on page C5-421
TLBI VMALLS12E1IS	*TLBI VMALLS12E1IS, TLB Invalidate by VMID, All at Stage 1 and 2, EL1, Inner Shareable* on page C5-422

K13.3.10 Base system registers

This section is an index to the registers in the functional group.

Table K13-15 Base system registers

Register	Description, see
ACTLR_EL1	*ACTLR_EL1, Auxiliary Control Register (EL1)* on page D7-1810
ACTLR_EL2	*ACTLR_EL2, Auxiliary Control Register (EL2)* on page D7-1811
ACTLR_EL3	*ACTLR_EL3, Auxiliary Control Register (EL3)* on page D7-1812
AFSR0_EL1	*AFSR0_EL1, Auxiliary Fault Status Register 0 (EL1)* on page D7-1813
AFSR0_EL2	*AFSR0_EL2, Auxiliary Fault Status Register 0 (EL2)* on page D7-1814

K13.4 Alphabetical index of AArch32 registers and system instructions

This section is an index of AArch32 registers and system instructions in alphabetical order.

Table K13-16 Alphabetical index of AArch32 Registers

Register	Description, see
ACTLR	*ACTLR, Auxiliary Control Register* on page G6-4086
ACTLR2	*ACTLR2, Auxiliary Control Register 2* on page G6-4088
ADFSR	*ADFSR, Auxiliary Data Fault Status Register* on page G6-4090
AIDR	*AIDR, Auxiliary ID Register* on page G6-4092
AIFSR	*AIFSR, Auxiliary Instruction Fault Status Register* on page G6-4094
AMAIR0	*AMAIR0, Auxiliary Memory Attribute Indirection Register 0* on page G6-4096
AMAIR1	*AMAIR1, Auxiliary Memory Attribute Indirection Register 1* on page G6-4098
APSR	*APSR, Application Program Status Register* on page G6-4100
ATS12NSOPR	*ATS12NSOPR, Address Translate Stages 1 and 2 Non-secure Only PL1 Read* on page G6-4102
ATS12NSOPW	*ATS12NSOPW, Address Translate Stages 1 and 2 Non-secure Only PL1 Write* on page G6-4104
ATS12NSOUR	*ATS12NSOUR, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Read* on page G6-4106
ATS12NSOUW	*ATS12NSOUW, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Write* on page G6-4108
ATS1CPR	*ATS1CPR, Address Translate Stage 1 Current state PL1 Read* on page G6-4110
ATS1CPW	*ATS1CPW, Address Translate Stage 1 Current state PL1 Write* on page G6-4112
ATS1CUR	*ATS1CUR, Address Translate Stage 1 Current state Unprivileged Read* on page G6-4114
ATS1CUW	*ATS1CUW, Address Translate Stage 1 Current state Unprivileged Write* on page G6-4116
ATS1HR	*ATS1HR, Address Translate Stage 1 Hyp mode Read* on page G6-4118
ATS1HW	*ATS1HW, Address Translate Stage 1 Hyp mode Write* on page G6-4120
BPIALL	*BPIALL, Branch Predictor Invalidate All* on page G6-4122
BPIALLIS	*BPIALLIS, Branch Predictor Invalidate All, Inner Shareable* on page G6-4123
BPIMVA	*BPIMVA, Branch Predictor Invalidate by VA* on page G6-4124
CCSIDR	*CCSIDR, Current Cache Size ID Register* on page G6-4126
CLIDR	*CLIDR, Cache Level ID Register* on page G6-4129
CNTFRQ	*CNTFRQ, Counter-timer Frequency register* on page G6-4655
CNTHCTL	*CNTHCTL, Counter-timer Hyp Control register* on page G6-4657
CNTHP_CTL	*CNTHP_CTL, Counter-timer Hyp Physical Timer Control register* on page G6-4659
CNTHP_CVAL	*CNTHP_CVAL, Counter-timer Hyp Physical CompareValue register* on page G6-4661
CNTHP_TVAL	*CNTHP_TVAL, Counter-timer Hyp Physical Timer TimerValue register* on page G6-4663
CNTKCTL	*CNTKCTL, Counter-timer Kernel Control register* on page G6-4665

K13.5 Functional index of AArch32 registers and system instructions

This section is an index of the AArch32 registers and system instructions, divided by functional group. Each of the following sections lists the registers for a functional group:

- *Special-purpose registers*.
- *VMSA-specific registers* on page K13-5600.
- *ID registers* on page K13-5600.
- *Performance monitors registers* on page K13-5602.
- *Debug registers* on page K13-5602.
- *Generic timer registers* on page K13-5604.
- *Cache maintenance system instructions* on page K13-5604.
- *Address translation system instructions* on page K13-5605.
- *TLB maintenance system instructions* on page K13-5605.
- *Legacy feature registers and system instructions* on page K13-5607.
- *Base system registers* on page K13-5607.

K13.5.1 Special-purpose registers

This section is an index to the registers in the Processor state registers functional group.

Table K13-17 Special-purpose registers

Register	Description, see
DLR	*DLR, Debug Link Register* on page G6-4595
DSPSR	*DSPSR, Debug Saved Program Status Register* on page G6-4597
ELR_hyp	*ELR_hyp, Exception Link Register (Hyp mode)* on page G6-4180
FPSCR	*FPSCR, Floating-Point Status and Control Register* on page G6-4189
SPSR	*SPSR, Saved Program Status Register* on page G6-4407
SPSR_abt	*SPSR_abt, Saved Program Status Register (Abort mode)* on page G6-4410
SPSR_fiq	*SPSR_fiq, Saved Program Status Register (FIQ mode)* on page G6-4414
SPSR_hyp	*SPSR_hyp, Saved Program Status Register (Hyp mode)* on page G6-4418
SPSR_irq	*SPSR_irq, Saved Program Status Register (IRQ mode)* on page G6-4422
SPSR_mon	*SPSR_mon, Saved Program Status Register (Monitor mode)* on page G6-4426
SPSR_svc	*SPSR_svc, Saved Program Status Register (Sup. Call mode)* on page G6-4430
SPSR_und	*SPSR_und, Saved Program Status Register (Undefined mode)* on page G6-4434

Non-Confidential - Beta

K13.5.2 VMSA-specific registers

This section is an index to the registers in the Virtual memory control registers functional group.

Table K13-18 VMSA-specific registers

Register	Description, see
AMAIR0	*AMAIR0, Auxiliary Memory Attribute Indirection Register 0* on page G6-4096
AMAIR1	*AMAIR1, Auxiliary Memory Attribute Indirection Register 1* on page G6-4098
CONTEXTIDR	*CONTEXTIDR, Context ID Register* on page G6-4131
DACR	*DACR, Domain Access Control Register* on page G6-4150
HAMAIR0	*HAMAIR0, Hyp Auxiliary Memory Attribute Indirection Register 0* on page G6-4208
HAMAIR1	*HAMAIR1, Hyp Auxiliary Memory Attribute Indirection Register 1* on page G6-4210
HMAIR0	*HMAIR0, Hyp Memory Attribute Indirection Register 0* on page G6-4233
HMAIR1	*HMAIR1, Hyp Memory Attribute Indirection Register 1* on page G6-4236
HTCR	*HTCR, Hyp Translation Control Register* on page G6-4271
HTTBR	*HTTBR, Hyp Translation Table Base Register* on page G6-4276
MAIR0	*MAIR0, Memory Attribute Indirection Register 0* on page G6-4348
MAIR1	*MAIR1, Memory Attribute Indirection Register 1* on page G6-4351
NMRR	*NMRR, Normal Memory Remap Register* on page G6-4370
PRRR	*PRRR, Primary Region Remap Register* on page G6-4384
TTBCR	*TTBCR, Translation Table Base Control Register* on page G6-4496
TTBR0	*TTBR0, Translation Table Base Register 0* on page G6-4501
TTBR1	*TTBR1, Translation Table Base Register 1* on page G6-4505
VTCR	*VTCR, Virtualization Translation Control Register* on page G6-4516
VTTBR	*VTTBR, Virtualization Translation Table Base Register* on page G6-4519

K13.5.3 ID registers

This section is an index to the registers in the Identification registers functional group.

Table K13-19 ID registers

Register	Description, see
AIDR	*AIDR, Auxiliary ID Register* on page G6-4092
CCSIDR	*CCSIDR, Current Cache Size ID Register* on page G6-4126
CLIDR	*CLIDR, Cache Level ID Register* on page G6-4129
CSSELR	*CSSELR, Cache Size Selection Register* on page G6-4146
CTR	*CTR, Cache Type Register* on page G6-4148
FPSID	*FPSID, Floating-Point System ID register* on page G6-4195

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Table K13-19 ID registers (continued)

Register	Description, see
ID_AFR0	*ID_AFR0, Auxiliary Feature Register 0* on page G6-4286
ID_DFR0	*ID_DFR0, Debug Feature Register 0* on page G6-4288
ID_ISAR0	*ID_ISAR0, Instruction Set Attribute Register 0* on page G6-4291
ID_ISAR1	*ID_ISAR1, Instruction Set Attribute Register 1* on page G6-4294
ID_ISAR2	*ID_ISAR2, Instruction Set Attribute Register 2* on page G6-4297
ID_ISAR3	*ID_ISAR3, Instruction Set Attribute Register 3* on page G6-4300
ID_ISAR4	*ID_ISAR4, Instruction Set Attribute Register 4* on page G6-4303
ID_ISAR5	*ID_ISAR5, Instruction Set Attribute Register 5* on page G6-4306
ID_MMFR0	*ID_MMFR0, Memory Model Feature Register 0* on page G6-4308
ID_MMFR1	*ID_MMFR1, Memory Model Feature Register 1* on page G6-4311
ID_MMFR2	*ID_MMFR2, Memory Model Feature Register 2* on page G6-4315
ID_MMFR3	*ID_MMFR3, Memory Model Feature Register 3* on page G6-4319
ID_MMFR4	*ID_MMFR4, Memory Model Feature Register 4* on page G6-4322
ID_PFR0	*ID_PFR0, Processor Feature Register 0* on page G6-4324
ID_PFR1	*ID_PFR1, Processor Feature Register 1* on page G6-4326
MIDR	*MIDR, Main ID Register* on page G6-4354
MPIDR	*MPIDR, Multiprocessor Affinity Register* on page G6-4357
MVFR0	*MVFR0, Media and VFP Feature Register 0* on page G6-4361
MVFR1	*MVFR1, Media and VFP Feature Register 1* on page G6-4365
MVFR2	*MVFR2, Media and VFP Feature Register 2* on page G6-4368
REVIDR	*REVIDR, Revision ID Register* on page G6-4387
TCMTR	*TCMTR, TCM Type Register* on page G6-4438
TLBTR	*TLBTR, TLB Type Register* on page G6-4488
VMPIDR	*VMPIDR, Virtualization Multiprocessor ID Register* on page G6-4511
VPIDR	*VPIDR, Virtualization Processor ID Register* on page G6-4513

K13.5.4 Performance monitors registers

This section is an index to the registers in the Performance Monitors registers functional group.

Table K13-20 Performance monitors registers

Register	Description, see
PMCCFILTR	*PMCCFILTR, Performance Monitors Cycle Count Filter Register* on page G6-4611
PMCCNTR	*PMCCNTR, Performance Monitors Cycle Count Register* on page G6-4614
PMCEID0	*PMCEID0, Performance Monitors Common Event Identification register 0* on page G6-4617
PMCEID1	*PMCEID1, Performance Monitors Common Event Identification register 1* on page G6-4619
PMCNTENCLR	*PMCNTENCLR, Performance Monitors Count Enable Clear register* on page G6-4621
PMCNTENSET	*PMCNTENSET, Performance Monitors Count Enable Set register* on page G6-4623
PMCR	*PMCR, Performance Monitors Control Register* on page G6-4625
PMEVCNTR<n>	*PMEVCNTR<n>, Performance Monitors Event Count Registers, n = 0 - 30* on page G6-4629
PMEVTYPER<n>	*PMEVTYPER<n>, Performance Monitors Event Type Registers, n = 0 - 30* on page G6-4631
PMINTENCLR	*PMINTENCLR, Performance Monitors Interrupt Enable Clear register* on page G6-4635
PMINTENSET	*PMINTENSET, Performance Monitors Interrupt Enable Set register* on page G6-4637
PMOVSR	*PMOVSR, Performance Monitors Overflow Flag Status Register* on page G6-4639
PMOVSSET	*PMOVSSET, Performance Monitors Overflow Flag Status Set register* on page G6-4641
PMSELR	*PMSELR, Performance Monitors Event Counter Selection Register* on page G6-4643
PMSWINC	*PMSWINC, Performance Monitors Software Increment register* on page G6-4645
PMUSERENR	*PMUSERENR, Performance Monitors User Enable Register* on page G6-4647
PMXEVCNTR	*PMXEVCNTR, Performance Monitors Selected Event Count Register* on page G6-4650
PMXEVTYPER	*PMXEVTYPER, Performance Monitors Selected Event Type Register* on page G6-4652

K13.5.5 Debug registers

This section is an index to the registers in the Debug registers functional group.

Table K13-21 Debug registers

Register	Description, see
DBGAUTHSTATUS	*DBGAUTHSTATUS, Debug Authentication Status register* on page G6-4522
DBGBCR<n>	*DBGBCR<n>, Debug Breakpoint Control Registers, n = 0 - 15* on page G6-4524
DBGBVR<n>	*DBGBVR<n>, Debug Breakpoint Value Registers, n = 0 - 15* on page G6-4528
DBGBXVR<n>	*DBGBXVR<n>, Debug Breakpoint Extended Value Registers, n = 0 - 15* on page G6-4531
DBGCLAIMCLR	*DBGCLAIMCLR, Debug Claim Tag Clear register* on page G6-4533
DBGCLAIMSET	*DBGCLAIMSET, Debug Claim Tag Set register* on page G6-4535
DBGDCCINT	*DBGDCCINT, DCC Interrupt Enable Register* on page G6-4537

K13.5.6 Generic timer registers

This section is an index to the registers in the Generic Timer registers functional group.

Table K13-22 Generic timer registers

Register	Description, see
CNTFRQ	*CNTFRQ, Counter-timer Frequency register* on page G6-4655
CNTHCTL	*CNTHCTL, Counter-timer Hyp Control register* on page G6-4657
CNTHP_CTL	*CNTHP_CTL, Counter-timer Hyp Physical Timer Control register* on page G6-4659
CNTHP_CVAL	*CNTHP_CVAL, Counter-timer Hyp Physical CompareValue register* on page G6-4661
CNTHP_TVAL	*CNTHP_TVAL, Counter-timer Hyp Physical Timer TimerValue register* on page G6-4663
CNTKCTL	*CNTKCTL, Counter-timer Kernel Control register* on page G6-4665
CNTP_CTL	*CNTP_CTL, Counter-timer Physical Timer Control register* on page G6-4668
CNTP_CVAL	*CNTP_CVAL, Counter-timer Physical Timer CompareValue register* on page G6-4671
CNTP_TVAL	*CNTP_TVAL, Counter-timer Physical Timer TimerValue register* on page G6-4673
CNTPCT	*CNTPCT, Counter-timer Physical Count register* on page G6-4675
CNTV_CTL	*CNTV_CTL, Counter-timer Virtual Timer Control register* on page G6-4677
CNTV_CVAL	*CNTV_CVAL, Counter-timer Virtual Timer CompareValue register* on page G6-4679
CNTV_TVAL	*CNTV_TVAL, Counter-timer Virtual Timer TimerValue register* on page G6-4681
CNTVCT	*CNTVCT, Counter-timer Virtual Count register* on page G6-4683
CNTVOFF	*CNTVOFF, Counter-timer Virtual Offset register* on page G6-4685

K13.5.7 Cache maintenance system instructions

This section is an index to the registers in the Cache maintenance instructions functional group.

Table K13-23 Cache maintenance system instructions

Register	Description, see
BPIALL	*BPIALL, Branch Predictor Invalidate All* on page G6-4122
BPIALLIS	*BPIALLIS, Branch Predictor Invalidate All, Inner Shareable* on page G6-4123
BPIMVA	*BPIMVA, Branch Predictor Invalidate by VA* on page G6-4124
DCCIMVAC	*DCCIMVAC, Data Cache line Clean and Invalidate by VA to PoC* on page G6-4152
DCCISW	*DCCISW, Data Cache line Clean and Invalidate by Set/Way* on page G6-4154
DCCMVAC	*DCCMVAC, Data Cache line Clean by VA to PoC* on page G6-4156
DCCMVAU	*DCCMVAU, Data Cache line Clean by VA to PoU* on page G6-4158
DCCSW	*DCCSW, Data Cache line Clean by Set/Way* on page G6-4160
DCIMVAC	*DCIMVAC, Data Cache line Invalidate by VA to PoC* on page G6-4162
DCISW	*DCISW, Data Cache line Invalidate by Set/Way* on page G6-4164

Table K13-23 Cache maintenance system instructions (continued)

Register	Description, see
ICIALLU	*ICIALLU, Instruction Cache Invalidate All to PoU* on page G6-4280
ICIALLUIS	*ICIALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable* on page G6-4282
ICIMVAU	*ICIMVAU, Instruction Cache line Invalidate by VA to PoU* on page G6-4284

K13.5.8 Address translation system instructions

This section is an index to the registers in the Address translation instructions functional group.

Table K13-24 Address translation system instructions

Register	Description, see
ATS12NSOPR	*ATS12NSOPR, Address Translate Stages 1 and 2 Non-secure Only PL1 Read* on page G6-4102
ATS12NSOPW	*ATS12NSOPW, Address Translate Stages 1 and 2 Non-secure Only PL1 Write* on page G6-4104
ATS12NSOUR	*ATS12NSOUR, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Read* on page G6-4106
ATS12NSOUW	*ATS12NSOUW, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Write* on page G6-4108
ATS1CPR	*ATS1CPR, Address Translate Stage 1 Current state PL1 Read* on page G6-4110
ATS1CPW	*ATS1CPW, Address Translate Stage 1 Current state PL1 Write* on page G6-4112
ATS1CUR	*ATS1CUR, Address Translate Stage 1 Current state Unprivileged Read* on page G6-4114
ATS1CUW	*ATS1CUW, Address Translate Stage 1 Current state Unprivileged Write* on page G6-4116
ATS1HR	*ATS1HR, Address Translate Stage 1 Hyp mode Read* on page G6-4118
ATS1HW	*ATS1HW, Address Translate Stage 1 Hyp mode Write* on page G6-4120

K13.5.9 TLB maintenance system instructions

This section is an index to the registers in the TLB maintenance instructions functional group.

Table K13-25 TLB maintenance system instructions

Register	Description, see
DTLBIALL	*DTLBIALL, Data TLB Invalidate All* on page G6-4174
DTLBIASID	*DTLBIASID, Data TLB Invalidate by ASID match* on page G6-4176
DTLBIMVA	*DTLBIMVA, Data TLB Invalidate by VA* on page G6-4178
ITLBIALL	*ITLBIALL, Instruction TLB Invalidate All* on page G6-4338
ITLBIASID	*ITLBIASID, Instruction TLB Invalidate by ASID match* on page G6-4340
ITLBIMVA	*ITLBIMVA, Instruction TLB Invalidate by VA* on page G6-4342
TLBIALL	*TLBIALL, TLB Invalidate All* on page G6-4440

Non-Confidential - Beta

Table K13-25 TLB maintenance system instructions (continued)

Register	Description, see
TLBIALLH	*TLBIALLH, TLB Invalidate All, Hyp mode* on page G6-4442
TLBIALLHIS	*TLBIALLHIS, TLB Invalidate All, Hyp mode, Inner Shareable* on page G6-4444
TLBIALLIS	*TLBIALLIS, TLB Invalidate All, Inner Shareable* on page G6-4446
TLBIALLNSNH	*TLBIALLNSNH, TLB Invalidate All, Non-Secure Non-Hyp* on page G6-4448
TLBIALLNSNHIS	*TLBIALLNSNHIS, TLB Invalidate All, Non-Secure Non-Hyp, Inner Shareable* on page G6-4450
TLBIASID	*TLBIASID, TLB Invalidate by ASID match* on page G6-4452
TLBIASIDIS	*TLBIASIDIS, TLB Invalidate by ASID match, Inner Shareable* on page G6-4454
TLBIIPAS2	*TLBIIPAS2, TLB Invalidate by Intermediate Physical Address, Stage 2* on page G6-4456
TLBIIPAS2IS	*TLBIIPAS2IS, TLB Invalidate by Intermediate Physical Address, Stage 2, Inner Shareable* on page G6-4458
TLBIIPAS2L	*TLBIIPAS2L, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level* on page G6-4460
TLBIIPAS2LIS	*TLBIIPAS2LIS, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, Inner Shareable* on page G6-4462
TLBIMVA	*TLBIMVA, TLB Invalidate by VA* on page G6-4464
TLBIMVAA	*TLBIMVAA, TLB Invalidate by VA, All ASID* on page G6-4466
TLBIMVAAIS	*TLBIMVAAIS, TLB Invalidate by VA, All ASID, Inner Shareable* on page G6-4468
TLBIMVAAL	*TLBIMVAAL, TLB Invalidate by VA, All ASID, Last level* on page G6-4470
TLBIMVAALIS	*TLBIMVAALIS, TLB Invalidate by VA, All ASID, Last level, Inner Shareable* on page G6-4472
TLBIMVAH	*TLBIMVAH, TLB Invalidate by VA, Hyp mode* on page G6-4474
TLBIMVAHIS	*TLBIMVAHIS, TLB Invalidate by VA, Hyp mode, Inner Shareable* on page G6-4476
TLBIMVAIS	*TLBIMVAIS, TLB Invalidate by VA, Inner Shareable* on page G6-4478
TLBIMVAL	*TLBIMVAL, TLB Invalidate by VA, Last level* on page G6-4480
TLBIMVALH	*TLBIMVALH, TLB Invalidate by VA, Last level, Hyp mode* on page G6-4482
TLBIMVALHIS	*TLBIMVALHIS, TLB Invalidate by VA, Last level, Hyp mode, Inner Shareable* on page G6-4484
TLBIMVALIS	*TLBIMVALIS, TLB Invalidate by VA, Last level, Inner Shareable* on page G6-4486

K13.5.10 Legacy feature registers and system instructions

This section is an index to the registers in the Legacy feature registers functional group.

Table K13-26 Legacy feature registers and system instructions

Register	Description, see
CP15DMB	*CP15DMB, CP15 Data Memory Barrier operation* on page G6-4133
CP15DSB	*CP15DSB, CP15 Data Synchronization Barrier operation* on page G6-4135
CP15ISB	*CP15ISB, CP15 Instruction Synchronization Barrier operation* on page G6-4137
FCSEIDR	*FCSEIDR, FCSE Process ID register* on page G6-4182
JIDR	*JIDR, Jazelle ID Register* on page G6-4344
JMCR	*JMCR, Jazelle Main Configuration Register* on page G6-4346
JOSCR	*JOSCR, Jazelle OS Control Register* on page G6-4347

K13.5.11 Base system registers

This section is an index to the registers in the functional group.

Table K13-27 Base system registers

Register	Description, see
ACTLR	*ACTLR, Auxiliary Control Register* on page G6-4086
ACTLR2	*ACTLR2, Auxiliary Control Register 2* on page G6-4088
ADFSR	*ADFSR, Auxiliary Data Fault Status Register* on page G6-4090
AIFSR	*AIFSR, Auxiliary Instruction Fault Status Register* on page G6-4094
APSR	*APSR, Application Program Status Register* on page G6-4100
CPACR	*CPACR, Architectural Feature Access Control Register* on page G6-4139
CPSR	*CPSR, Current Program Status Register* on page G6-4143
DFAR	*DFAR, Data Fault Address Register* on page G6-4166
DFSR	*DFSR, Data Fault Status Register* on page G6-4168
FPEXC	*FPEXC, Floating-Point Exception Control register* on page G6-4184
HACR	*HACR, Hyp Auxiliary Configuration Register* on page G6-4198
HACTLR	*HACTLR, Hyp Auxiliary Control Register* on page G6-4200
HACTLR2	*HACTLR2, Hyp Auxiliary Control Register 2* on page G6-4202
HADFSR	*HADFSR, Hyp Auxiliary Data Fault Status Register* on page G6-4204
HAIFSR	*HAIFSR, Hyp Auxiliary Instruction Fault Status Register* on page G6-4206
HCPTR	*HCPTR, Hyp Architectural Feature Trap Register* on page G6-4212
HCR	*HCR, Hyp Configuration Register* on page G6-4216
HCR2	*HCR2, Hyp Configuration Register 2* on page G6-4226

K13.6 Alphabetical index of memory-mapped registers

This section is an index of memory-mapped registers in alphabetical order.

Table K13-28 Alphabetical index of Memory-Mapped Registers

Register	Description, see
ASICCTL	*ASICCTL, CTI External Multiplexer Control register* on page H9-4920
CNTACR<n>	*CNTACR<n>, Counter-timer Access Control Registers, n = 0 - 7* on page I3-5039
CNTCR	*CNTCR, Counter Control Register* on page I3-5041
CNTCV	*CNTCV, Counter Count Value register* on page I3-5043
CNTEL0ACR	*CNTEL0ACR, Counter-timer EL0 Access Control Register* on page I3-5045
CNTFID0	*CNTFID0, Counter Frequency ID* on page I3-5047
CNTFID<n>	*CNTFID<n>, Counter Frequency IDs, n = 1 - 23* on page I3-5048
CNTFRQ	*CNTFRQ, Counter-timer Frequency* on page I3-5049
CNTNSAR	*CNTNSAR, Counter-timer Non-secure Access Register* on page I3-5051
CNTP_CTL	*CNTP_CTL, Counter-timer Physical Timer Control* on page I3-5053
CNTP_CVAL	*CNTP_CVAL, Counter-timer Physical Timer CompareValue* on page I3-5055
CNTP_TVAL	*CNTP_TVAL, Counter-timer Physical Timer TimerValue* on page I3-5057
CNTPCT	*CNTPCT, Counter-timer Physical Count* on page I3-5058
CNTSR	*CNTSR, Counter Status Register* on page I3-5060
CNTTIDR	*CNTTIDR, Counter-timer Timer ID Register* on page I3-5062
CNTV_CTL	*CNTV_CTL, Counter-timer Virtual Timer Control* on page I3-5064
CNTV_CVAL	*CNTV_CVAL, Counter-timer Virtual Timer CompareValue* on page I3-5066
CNTV_TVAL	*CNTV_TVAL, Counter-timer Virtual Timer TimerValue* on page I3-5068
CNTVCT	*CNTVCT, Counter-timer Virtual Count* on page I3-5070
CNTVOFF	*CNTVOFF{<n>}, Counter-timer Virtual Offset* on page I3-5072
CNTVOFF<n>	*CNTVOFF{<n>}, Counter-timer Virtual Offset* on page I3-5072
CounterID<n>	*CounterID<n>, Counter ID registers, n = 0 - 11* on page I3-5074
CTIAPPCLEAR	*CTIAPPCLEAR, CTI Application Trigger Clear register* on page H9-4921
CTIAPPPULSE	*CTIAPPPULSE, CTI Application Pulse register* on page H9-4922
CTIAPPSET	*CTIAPPSET, CTI Application Trigger Set register* on page H9-4923
CTIAUTHSTATUS	*CTIAUTHSTATUS, CTI Authentication Status register* on page H9-4924
CTICHINSTATUS	*CTICHINSTATUS, CTI Channel In Status register* on page H9-4926
CTICHOUTSTATUS	*CTICHOUTSTATUS, CTI Channel Out Status register* on page H9-4927
CTICIDR0	*CTICIDR0, CTI Component Identification Register 0* on page H9-4928
CTICIDR1	*CTICIDR1, CTI Component Identification Register 1* on page H9-4929

Table K13-28 Alphabetical index of Memory-Mapped Registers (continued)

Register	Description, see
CTICIDR2	*CTICIDR2, CTI Component Identification Register 2* on page H9-4930
CTICIDR3	*CTICIDR3, CTI Component Identification Register 3* on page H9-4931
CTICLAIMCLR	*CTICLAIMCLR, CTI Claim Tag Clear register* on page H9-4932
CTICLAIMSET	*CTICLAIMSET, CTI Claim Tag Set register* on page H9-4933
CTICONTROL	*CTICONTROL, CTI Control register* on page H9-4934
CTIDEVAFF0	*CTIDEVAFF0, CTI Device Affinity register 0* on page H9-4935
CTIDEVAFF1	*CTIDEVAFF1, CTI Device Affinity register 1* on page H9-4936
CTIDEVARCH	*CTIDEVARCH, CTI Device Architecture register* on page H9-4937
CTIDEVID	*CTIDEVID, CTI Device ID register 0* on page H9-4939
CTIDEVID1	*CTIDEVID1, CTI Device ID register 1* on page H9-4941
CTIDEVID2	*CTIDEVID2, CTI Device ID register 2* on page H9-4942
CTIDEVTYPE	*CTIDEVTYPE, CTI Device Type register* on page H9-4943
CTIGATE	*CTIGATE, CTI Channel Gate Enable register* on page H9-4944
CTIINEN<n>	*CTIINEN<n>, CTI Input Trigger to Output Channel Enable registers, n = 0 - 31* on page H9-4945
CTIINTACK	*CTIINTACK, CTI Output Trigger Acknowledge register* on page H9-4946
CTIITCTRL	*CTIITCTRL, CTI Integration mode Control register* on page H9-4948
CTILAR	*CTILAR, CTI Lock Access Register* on page H9-4949
CTILSR	*CTILSR, CTI Lock Status Register* on page H9-4950
CTIOUTEN<n>	*CTIOUTEN<n>, CTI Input Channel to Output Trigger Enable registers, n = 0 - 31* on page H9-4952
CTIPIDR0	*CTIPIDR0, CTI Peripheral Identification Register 0* on page H9-4953
CTIPIDR1	*CTIPIDR1, CTI Peripheral Identification Register 1* on page H9-4954
CTIPIDR2	*CTIPIDR2, CTI Peripheral Identification Register 2* on page H9-4955
CTIPIDR3	*CTIPIDR3, CTI Peripheral Identification Register 3* on page H9-4956
CTIPIDR4	*CTIPIDR4, CTI Peripheral Identification Register 4* on page H9-4957
CTITRIGINSTATUS	*CTITRIGINSTATUS, CTI Trigger In Status register* on page H9-4958
CTITRIGOUTSTATUS	*CTITRIGOUTSTATUS, CTI Trigger Out Status register* on page H9-4959
DBGAUTHSTATUS_EL1	*DBGAUTHSTATUS_EL1, Debug Authentication Status register* on page H9-4834
DBGBCR<n>_EL1	*DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 15* on page H9-4836
DBGBVR<n>_EL1	*DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 15* on page H9-4839
DBGCLAIMCLR_EL1	*DBGCLAIMCLR_EL1, Debug Claim Tag Clear register* on page H9-4842
DBGCLAIMSET_EL1	*DBGCLAIMSET_EL1, Debug Claim Tag Set register* on page H9-4844
DBGDTRRX_EL0	*DBGDTRRX_EL0, Debug Data Transfer Register, Receive* on page H9-4846

K13.7.4 Cross-trigger interface registers

This section is an index to the registers in the Cross-Trigger Interface registers functional group.

Table K13-32 Cross-trigger interface registers

Register	Description, see
ASICCTL	*ASICCTL, CTI External Multiplexer Control register* on page H9-4920
CTIAPPCLEAR	*CTIAPPCLEAR, CTI Application Trigger Clear register* on page H9-4921
CTIAPPPULSE	*CTIAPPPULSE, CTI Application Pulse register* on page H9-4922
CTIAPPSET	*CTIAPPSET, CTI Application Trigger Set register* on page H9-4923
CTIAUTHSTATUS	*CTIAUTHSTATUS, CTI Authentication Status register* on page H9-4924
CTICHINSTATUS	*CTICHINSTATUS, CTI Channel In Status register* on page H9-4926
CTICHOUTSTATUS	*CTICHOUTSTATUS, CTI Channel Out Status register* on page H9-4927
CTICIDR0	*CTICIDR0, CTI Component Identification Register 0* on page H9-4928
CTICIDR1	*CTICIDR1, CTI Component Identification Register 1* on page H9-4929
CTICIDR2	*CTICIDR2, CTI Component Identification Register 2* on page H9-4930
CTICIDR3	*CTICIDR3, CTI Component Identification Register 3* on page H9-4931
CTICLAIMCLR	*CTICLAIMCLR, CTI Claim Tag Clear register* on page H9-4932
CTICLAIMSET	*CTICLAIMSET, CTI Claim Tag Set register* on page H9-4933
CTICONTROL	*CTICONTROL, CTI Control register* on page H9-4934
CTIDEVAFF0	*CTIDEVAFF0, CTI Device Affinity register 0* on page H9-4935
CTIDEVAFF1	*CTIDEVAFF1, CTI Device Affinity register 1* on page H9-4936
CTIDEVARCH	*CTIDEVARCH, CTI Device Architecture register* on page H9-4937
CTIDEVID	*CTIDEVID, CTI Device ID register 0* on page H9-4939
CTIDEVID1	*CTIDEVID1, CTI Device ID register 1* on page H9-4941
CTIDEVID2	*CTIDEVID2, CTI Device ID register 2* on page H9-4942
CTIDEVTYPE	*CTIDEVTYPE, CTI Device Type register* on page H9-4943
CTIGATE	*CTIGATE, CTI Channel Gate Enable register* on page H9-4944
CTIINEN<n>	*CTIINEN<n>, CTI Input Trigger to Output Channel Enable registers, n = 0 - 31* on page H9-4945
CTIINTACK	*CTIINTACK, CTI Output Trigger Acknowledge register* on page H9-4946
CTIITCTRL	*CTIITCTRL, CTI Integration mode Control register* on page H9-4948
CTILAR	*CTILAR, CTI Lock Access Register* on page H9-4949
CTILSR	*CTILSR, CTI Lock Status Register* on page H9-4950
CTIOUTEN<n>	*CTIOUTEN<n>, CTI Input Channel to Output Trigger Enable registers, n = 0 - 31* on page H9-4952
CTIPIDR0	*CTIPIDR0, CTI Peripheral Identification Register 0* on page H9-4953

Glossary

Note

The update of the Glossary from ARMv7 to ARMv8 remains work-in-progress.

A32 instruction A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in A32 state. A32 instructions must be word-aligned.

A32 instructions were previously called ARM instructions.

See also A32 state, A64 instruction, T32 instruction.

A32 state The AArch32 Instruction set state in which the PE executes A32 instructions.

A32 state was previously called ARM state.

See also T32 instruction, T32 state.

A64 instruction A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch64. A64 instructions must be word-aligned.

See also A32 instruction, T32 instruction.

AArch32 The 32-bit Execution state. In AArch32 state, addresses are held in 32-bit registers, and instructions in the base instruction sets use 32-bit registers for their processing. AArch32 state supports the T32 and A32 instruction sets

See also AArch64, A32 instruction, T32 instruction.

AArch64 The 64-bit Execution state. In AArch64 state, addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.

See also AArch32, A64 instruction.

Non-Confidential - Beta

Abort An exception caused by an illegal memory access. Aborts can be caused by the external memory system or the MMU.

Addressing mode
Means a method for generating the memory address used by a load/store instruction.

Advanced SIMD A feature of the ARM architecture that provides SIMD operations on a register file of SIMD and floating-point registers. Where an implementation supports both Advanced SIMD and floating-point instructions, these instructions operate on the same register file.

Aligned A data item stored at an address that is exactly divisible by the highest power of 2 that divides exactly into its size in bytes. Aligned halfwords, words and doublewords therefore have addresses that are divisible by 2, 4 and 8 respectively.

An aligned access is one where the address of the access is aligned to the size of each element of the access.

Architecturally executed
An instruction is architecturally executed only if it would be executed in a simple sequential execution of the program. When such an instruction has been executed and retired it has been *architecturally executed*. Any instruction that, in a simple sequential execution of a program, is treated as a `NOP` because it fails its condition code check, is an architecturally executed instruction.

In a PE that performs speculative execution, an instruction is not architecturally executed if the PE discards the results of a speculative execution.

See also Condition code check, Simple sequential execution.

Architecturally mapped
Where this manual describes a register as being *architecturally mapped* to another register, this indicates that, in an implementation that supports both of the registers, the two registers access the same state.

Architecturally UNKNOWN
An architecturally UNKNOWN value is a value that is not defined by the architecture but must meet the requirements of the definition of UNKNOWN. Implementations can define the value of the field, but are not required to do so.

See also IMPLEMENTATION DEFINED.

ARM core registers
Some older documentation uses *ARM core registers* to refer to the following set of registers for execution in AArch32 state:

- The 13 general-purpose registers, R0-R12, that software can use for processing.
- SP, the *stack pointer*, that can also be referred to as R13.
- LR, the *link register*, that can also be referred to as R14.
- PC, the *program counter*, that can also be referred to as R15.

See also General-purpose registers.

ARM instruction
See A32 instruction.

Associativity *See* Cache associativity.

Atomicity Describes either single-copy atomicity or multi-copy atomicity. *Atomicity in the ARM architecture* on page B2-80 defines these forms of atomicity for the ARM architecture.

See also Multi-copy atomicity, Single-copy atomicity.

Banked register A register that has multiple instances, with the instance that is in use depending on the PE mode, Security state, or other PE state.

Base register A register specified by a load/store instruction that is used as the base value for the address calculation for the instruction. Depending on the instruction and its addressing mode, an offset can be added to or subtracted from the base register value to form the virtual address that is sent to memory.

Base register writeback
Describes writing back a modified value to the base register used in an address calculation.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Behaves as if Where this manual indicates that a PE *behaves as if* a certain condition applies, all descriptions of the operation of the PE must be re-evaluated taking account of that condition, together with any other conditions that affect operation.

Big-endian memory

Means that, for example:

- A byte or halfword at a word-aligned address is the most significant byte or halfword in the word at that address.
- A byte at a halfword-aligned address is the most significant byte in the halfword at that address.

See also Endianness, Little-endian memory.

Blocking Describes an operation that does not permit following instructions to be executed before the operation completes.

A non-blocking operation can permit following instructions to be executed before the operation completes, and in the event of encountering an exception does not signal an exception to the PE. This enables implementations to retire following instructions while the non-blocking operation is executing, without the need to retain precise PE state.

Branch prediction

Is where a PE selects a future execution path to fetch along. For example, after a branch instruction, the PE can choose to speculatively fetch either the instruction following the branch or the instruction at the branch target.

See also Prefetching.

Breakpoint A debug event triggered by the execution of a particular instruction, specified by one or both of the address of the instruction and the state of the PE when the instruction is executed.

Byte An 8-bit data item.

Cache associativity

The number of locations in a cache set to which an address can be assigned. Each location is identified by its *way* value.

Cache level The position of a cache in the cache hierarchy. In the ARM architecture, the lower numbered levels are those closest to the PE. For more information, see *Terms used in describing the maintenance instructions* on page D3-1623.

Cache line The basic unit of storage in a cache. Its size in words is always a power of two, usually 4 or 8 words. A cache line must be aligned to a suitable memory boundary. A *memory cache line* is a block of memory locations with the same size and alignment as a cache line. Memory cache lines are sometimes loosely called cache lines.

Cache lockdown

Enables critical software and data to be loaded into the cache so that the cache lines containing them are not subsequently reallocated. It alleviates the delays caused by accessing a cache in a worst-case situation. This ensures that all subsequent accesses to the software and data concerned are cache hits and so complete quickly.

Cache miss A memory access that cannot be processed at high speed because the data it addresses is not in the cache.

Cache sets Areas of a cache, divided up to simplify and speed up the process of determining whether a cache hit occurs. The number of cache sets is always a power of two.

Cache way A cache way consists of one cache line from each cache set. The cache ways are indexed from 0 to (Associativity-1). Each cache line in a cache way is chosen to have the same index as the cache way. For example, cache way *n* consists of the cache line with index *n* from each cache set.

Coherence order

See Coherent.

Coherent Data accesses from a set of observers to a byte in memory are coherent if accesses to that byte in memory by the members of that set of observers are consistent with there being a single total order of all writes to that byte in memory by all members of the set of observers. This single total order of all to writes to that memory location is the *coherence order* for that byte in memory.

Non-Confidential - Beta

Condition code check

The process of determining whether a conditional instruction executes normally or is treated as a `NOP`. For an instruction that includes a condition code field, that field is compared with the condition flags to determine whether the instruction is executed normally. For a T32 instruction in an IT block, the value of PSTATE.IT determines whether the instruction is executed normally.

See also Condition code field, Condition flags, Conditional execution.

Condition code field

A 4-bit field in an instruction that specifies the condition under which the instruction executes.

See also Condition code check.

Condition flags

The N, Z, C, and V bits of PSTATE, an SPSR, or FPSCR. See the register descriptions for more information.

See also Condition code check, PSTATE.

Conditional execution

When a conditional instruction starts executing, if the condition code check returns TRUE, the instruction executes normally. Otherwise, it is treated as a `NOP`.

See also Condition code check.

CONSTRAINED UNPREDICTABLE

Where an instruction can result in UNPREDICTABLE behavior, the ARMv8 architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

Execution at Non-secure EL1 or EL0 of an instruction that is CONSTRAINED UNPREDICTABLE can be implemented as generating a trap exception that is taken to EL2, provided that at least one instruction that is not UNPREDICTABLE and is not CONSTRAINED UNPREDICTABLE causes a trap exception that is taken to EL2.

In body text, the term CONSTRAINED UNPREDICTABLE is shown in SMALL CAPITALS.

See also UNPREDICTABLE.

Context switch

The saving and restoring of computational state when switching between different threads or processes. In this manual, the term context switch describes any situation where the context is switched by an operating system and might or might not include changes to the address space.

Context synchronization operation

One of:

- Performing an ISB operation. An ISB operation is performed when an `ISB` instruction is executed and does not fail its condition code check.
- Taking an exception.
- Returning from an exception.
- Exit from Debug state.
- Executing a `DCPS` instruction.
- Executing a `DRPS` instruction.

The architecture requires a context synchronization operation to guarantee visibility of any change to a System register.

Debugger

In most of this manual, *debugger* refers to any agent that is performing debug. However, some parts of the manual require a more rigorous definition, and define debugger locally. See:

- *Definition of a debugger* on page D2-1554 for the definition that applies to Chapter D2.
- *Definition of a debugger* on page G2-3778 for the definition that applies to Chapter G2.
- *Definition of a debugger* on page H1-4690 for the definition that applies to Part H.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Deprecated Something that is present in the ARM architecture for backwards compatibility. Whenever possible software must avoid using deprecated features. Features that are deprecated but are not optional are present in current implementations of the ARM architecture, but might not be present, or might be deprecated and OPTIONAL, in future versions of the ARM architecture.

See also OPTIONAL.

Digital signal processing (DSP)
Algorithms for processing signals that have been sampled and converted to digital form. DSP algorithms often use saturated arithmetic.

Direct Memory Access (DMA)
An operation that accesses main memory directly, without the PE performing any accesses to the data concerned.

Direct read A direct read of a System register is a read performed by a System register access instruction.

For more information, see *Direct read* on page D7-1804.

See also Direct write, Indirect read, Indirect write.

Direct write A direct write of a System register is a write performed by a System register access instruction.

For more information, see *Direct write* on page D7-1804.

See also Direct read, Indirect read, Indirect write.

DMA *See* Direct Memory Access (DMA).

DNM *See* Do-Not-Modify (DNM).

Domain In the ARM architecture, *domain* is used in the following contexts.

Shareability domain Defines a set of observers for which the shareability attributes make the data or unified caches transparent for data accesses.

Power domain Defines a block of logic with a single, common, power supply.

Memory regions domain
When using the Short-descriptor translation table format, defines a collection of Sections, Large pages and Small pages of memory, that can have their access permissions switched rapidly by writing to the *Domain Access Control Register* (DACR). ARM deprecates any use of memory regions domains.

Do-Not-Modify (DNM)
Means the value must not be altered by software. DNM fields read as UNKNOWN values, and must only be written with the value read from the same field on the same PE.

Double-precision value
Consists of two consecutive 32-bit words that are interpreted as a basic double-precision floating-point number according to the *IEEE Standard for Floating-point Arithmetic*.

Doubleword A 64-bit data item. Doublewords are normally at least word-aligned in ARM systems.

Doubleword-aligned
Means that the address is divisible by 8.

DSP *See* Digital signal processing (DSP).

Endianness An aspect of the system memory mapping.

See also Big-endian memory and Little-endian memory.

Exception Handles an event. For example, an exception could handle an external interrupt or an undefined instruction.

Exception vector
A fixed address that contains the address of the first instruction of the corresponding exception handler.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Execution stream
The stream of instructions that would have been executed by sequential execution of the program.

Explicit access A read from memory, or a write to memory, generated by a load or store instruction executed by the PE. Reads and writes generated by hardware translation table accesses are not explicit accesses.

External abort An abort that is generated by the external memory system.

Fast Context Switch Extension (FCSE)
Modifies the behavior of an ARM memory system to enable multiple programs running on the ARM PE to use identical address ranges, while ensuring that the addresses they present to the rest of the memory system differ. From ARMv6, ARM deprecates any use of the FCSE. The FCSE is:

- Optional in an ARMv7 implementation that does not include the Multiprocessing Extensions.
- Obsolete from the introduction of the Multiprocessing Extensions.

FCSE *See* Fast Context Switch Extension (FCSE).

Flat address mapping
Is where the physical address for every access is equal to its virtual address.

Flush-to-zero mode
A processing mode that optimizes the performance of some floating-point algorithms by replacing the denormalized operands and intermediate results with zeros, without significantly affecting the accuracy of their final results.

General-purpose registers
The registers that the base instructions use for processing:

- In AArch32 state the general-purpose registers are R0-R14, that can also be described as R0-R12, SP, LR.

  Note

  Older documentation defines the AArch32 general-purpose registers as R0-R12, and the ARM core registers as R0-R12, SP, LR, and PC.

- In AArch64 state the general-purpose registers are:
  — W0-W30 when accessed as 32-bit registers.
  — X0-X30 when accessed as 64-bit registers.

See also High registers, Low registers.

Halfword A 16-bit data item. Halfwords are normally halfword-aligned in ARM systems.

Halfword-aligned
Means that the address is divisible by 2.

High registers In AArch32 state, the general-purpose registers R8-R14. Most 16-bit T32 instructions cannot access the high registers.

Note

- In some contexts, *high registers* refers to R8-R15, meaning R8-R14 and the PC.

See also General-purpose registers, Low registers.

High vectors An alternative location for the exception vectors. The high vector address range is near the top of the address space, rather than at the bottom.

IGNORED Indicates that the architecture guarantees that the bit or field is not interpreted or modified by hardware.

In body text, the term IGNORED is shown in SMALL CAPITALS.

Immediate and offset fields
Are unsigned unless otherwise stated.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Immediate value
A value that is encoded directly in the instruction and used as numeric data when the instruction is executed. Many A64, A32, and T32 instructions can be used with an immediate argument.

IMP An abbreviation used in diagrams to indicate that one or more bits have IMPLEMENTATION DEFINED behavior.

IMPLEMENTATION DEFINED
Means that the behavior is not architecturally defined, but must be defined and documented by individual implementations.

In body text, the term IMPLEMENTATION DEFINED is shown in SMALL CAPITALS.

Index register A register specified in some load and store instructions. The value of this register is used as an offset to be added to or subtracted from the base register value to form the virtual address that is sent to memory. Some instruction forms permit the index register value to be shifted before the addition or subtraction.

Indirect read When an instruction uses a System register value to establish operating conditions, that use of the System register is an indirect read of the System register.

For more information, including additional examples of indirect reads, see *Indirect read* on page D7-1804.

See also Direct read, Direct write, Indirect write.

Indirect write An indirect write of a System register occurs when the contents of a register are updated by some mechanism other than a *Direct write* to that register. For example, an indirect write to a register might occur as a side-effect of executing an instruction that does not perform a direct write to the register, or because of some operation performed by an external agent.

For more information, see *Indirect write* on page D7-1804.

See also Direct read, Direct write, Indirect read.

Inline literals These are constant addresses and other data items held in the same area as the software itself. They are automatically generated by compilers, and can also appear in assembler code.

Intermediate physical address (IPA)
An implementation of virtualization, the address to which a Guest OS maps a VA. A hypervisor might then map the IPA to a PA. Typically, the Guest OS is unaware of the translation from IPA to PA.

See also Physical address (PA), Virtual address (VA).

Interworking A method of working that permits branches between software using the A32 and T32 instruction sets.

IPA *See* Intermediate physical address (IPA).

Level *See* Cache level.

Level of Coherence (LoC)
The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of coherency. For more information, see *Terms used in describing the maintenance instructions* on page D3-1623.

See also Cache level, Point of coherency (PoC).

Level of Unification, Inner Shareable (LoUIS)
The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for the Inner Shareable shareability domain. For more information, see *Terms used in describing the maintenance instructions* on page D3-1623.

See also Cache level, Point of unification (PoU).

Level of Unification, uniprocessor (LoUU)
For a PE, the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for that PE. For more information, see *Terms used in describing the maintenance instructions* on page D3-1623.

See also Cache level, Point of unification (PoU).

Line *See* Cache line.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Little-endian memory
Means that, for example:

- A byte or halfword at a word-aligned address is the least significant byte or halfword in the word at that address.
- A byte at a halfword-aligned address is the least significant byte in the halfword at that address.

See also Big-endian memory, Endianness.

Load/Store architecture
An architecture where data-processing operations only operate on register contents, not directly on memory contents.

LoC *See* Level of Coherence (LoC).

LoUIS *See* Level of Unification, Inner Shareable (LoUIS).

LoUU *See* Level of Unification, uniprocessor (LoUU).

Lockdown *See* Cache lockdown.

Low registers InAArch32 state, general-purpose registers R0-R7. Unlike the high registers, all T32 instructions can access the Low registers.

See also General-purpose registers, High registers.

Memory barrier *See Memory barriers* on page B2-86.

Memory coherency
The problem of ensuring that when a memory location is read, either by a data read or an instruction fetch, the value actually obtained is always the value that was most recently written to the location. This can be difficult when there are multiple possible physical locations, such as main memory and at least one of a write buffer and one or more levels of cache.

Memory Management Unit (MMU)
Provides detailed control of the part of a memory system that provides a single stage of address translation. Most of the control is provided using translation tables that are held in memory, and define the attributes of different regions of the physical memory map.

Memory Protection Unit (MPU)
A hardware unit whose registers provide simple control of a limited number of protection regions in memory.

Miss *See* Cache miss.

MMU *See* Memory Management Unit (MMU).

MPU *See* Memory Protection Unit (MPU).

Multi-copy atomicity
The form of atomicity described in *Requirements for multi-copy atomicity* on page B2-81.

See also Atomicity, Single-copy atomicity.

NaN

- Not a Number. A floating-point value that can be used when neither a numeric value nor an infinity is appropriate. A NaN can be a *quiet* NaN, that propagate through most floating-point operations, or a *signaling* NaN, that causes an Invalid Operation floating-point exception when used. For more information, see the *IEEE Standard for Floating-point Arithmetic*.

Natural eviction A natural eviction is an eviction that occurs in the course of the normal operation of the memory system, rather than because of an operation that explicitly causes an eviction from the cache, such as the execution of a cache maintenance instruction. Typically, a natural eviction occurs when the caching algorithm requires data to be cached but the cache does not have room for that data.

Observer A PE or mechanism in the system, such as a peripheral device, that can generate reads from or writes to memory.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Obsolete Obsolete indicates something that is no longer supported by ARM. When an architectural feature is described as obsolete, this indicates that the architecture has no support for that feature, although an earlier version of the architecture did support it.

Offset addressing
Means that the memory address is formed by adding or subtracting an offset to or from the base register value.

OPTIONAL When applied to a feature of the architecture, OPTIONAL indicates a feature that is not required in an implementation of the ARM architecture:

- If a feature is OPTIONAL and deprecated, this indicates that the feature is being phased out of the architecture. ARM expects such a features to be included in a new implementation only if there is a known backwards-compatibility reason for the inclusion of the feature.

  A feature that is OPTIONAL and deprecated might not be present in future versions of the architecture.

- A feature that is OPTIONAL but not deprecated is, typically, a feature added to a version of the ARM architecture after the initial release of that version of the architecture. ARM recommends that such features are included in all new implementations of the architecture.

In body text, these meanings of the term OPTIONAL are shown in SMALL CAPITALS.

Note: Do not confuse these ARM-specific uses of OPTIONAL with other uses of *optional*, where it has its usual meaning. These include:

- Optional arguments in the syntax of many instructions.
- Behavior determined by an implementation choice, for example the optional byte order reversal in an ARMv7-R implementation, where the SCTLR.IE bit indicates the implemented option.

See also Deprecated.

PA *See* Physical address (PA).

PE *See* Processing element (PE).

Physical address (PA)
An address that identifies a location in the physical memory map.

See also Intermediate physical address (IPA), Virtual address (VA).

PoC *See* Point of coherency (PoC).

PoU *See* Point of unification (PoU).

Point of coherency (PoC)
For a particular MVA, the point at which all agents that can access memory are guaranteed to see the same copy of a memory location. For more information, see *Terms used in describing the maintenance instructions* on page D3-1623.

Point of unification (PoU)
For a particular PE, the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. For more information, see *Terms used in describing the maintenance instructions* on page D3-1623.

Post-indexed addressing
Means that the memory address is the base register value, but an offset is added to or subtracted from the base register value and the result is written back to the base register.

Prefetching Prefetching refers to speculatively fetching instructions or data from the memory system. In particular, instruction prefetching is the process of fetching instructions from memory before the instructions that precede them, in simple sequential execution of the program, have finished executing. Prefetching an instruction does not mean that the instruction has to be executed.

In this manual, references to instruction or data fetching apply also to prefetching, unless the context explicitly indicates otherwise.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Note

The Prefetch Abort exception can be generated on any instruction fetch, and is not limited to speculative instruction fetches.

See also Simple sequential execution.

Pre-indexed addressing
Means that the memory address is formed in the same way as for offset addressing, but the memory address is also written back to the base register.

Processing element (PE)
The abstract machine defined in the ARM architecture, as documented in an ARM Architecture Reference Manual. A PE implementation compliant with the ARM architecture must conform with the behaviors described in the corresponding ARM Architecture Reference Manual.

Protection region
A memory region whose position, size, and other properties are defined by Memory Protection Unit registers.

Protection Unit *See* Memory Protection Unit (MPU).

Pseudo-instruction
UAL assembler syntax that assembles to an instruction encoding that is expected to disassemble to a different assembler syntax, and is described in this manual under that other syntax. For example, `MOV <Rd>, <Rm>, LSL #<n>` is a pseudo-instruction that is expected to disassemble as `LSL <Rd>, <Rm>, #<n>`.

PSTATE An abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

See also Condition flags.

Quadword A 128-bit data item. Quadwords are normally at least word-aligned in ARM systems.

Quadword-aligned
Means that the address is divisible by 16.

Quiet NaN A NaN that propagates unchanged through most floating-point operations.

RAO *See* Read-As-One (RAO).

RAZ *See* Read-As-Zero (RAZ).

RAO/SBOP In versions of the ARM architecture before ARMv8, Read-As-One, Should-Be-One-or-Preserved on writes.

In ARMv8, RES1 replaces this description.

See also UNK/SBOP, Read-As-One (RAO), RES1, Should-Be-One-or-Preserved (SBOP).

RAO/WI Read-As-One, Writes Ignored.

Hardware must implement the field as Read-as-One, and must ignore writes to the field.

Software can rely on the field reading as all 1s, and on writes being ignored.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

See also Read-As-One (RAO).

RAZ/SBZP In versions of the ARM architecture before ARMv8, Read-As-Zero, Should-Be-Zero-or-Preserved on writes.

In ARMv8, RES0 replaces this description.

See also UNK/SBZP, Read-As-Zero (RAZ), RES0, Should-Be-Zero-or-Preserved (SBZP).

RAZ/WI Read-As-Zero, Writes Ignored.

Hardware must implement the field as Read-as-Zero, and must ignore writes to the field.

Software can rely on the field reading as all 0s, and on writes being ignored.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.

See also Read-As-Zero (RAZ).

Read-allocate cache

A cache in which a cache miss on reading data causes a cache line to be allocated into the cache.

Read-As-One (RAO)

Hardware must implement the field as reading as all 1s.

Software:

- Can rely on the field reading as all 1s.
- Must use a SBOP policy to write to the field.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

Read-As-Zero (RAZ)

Hardware must implement the field as reading as all 0s.

Software:

- Can rely on the field reading as all 0s
- Must use a SBZP policy to write to the field.

This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.

Read, modify, write

In a read, modify, write instruction sequence, a value is read to a general-purpose register, the relevant fields updated in that register, and the new value written back.

RES0

A reserved bit or field with *Should-Be-Zero-or-Preserved (SBZP)* behavior. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory, for example in translation table descriptors.

Within the architecture, there are some cases where a register bit or bitfield:

- Is RES0 in some defined architectural context.
- Has different defined behavior in a different architectural context.

Note

- RES0 is not used in descriptions of instruction encodings.
- Where an AArch32 System register is *Architecturally mapped* to an AArch64 System register, and a bit or field in that register is RES0 in one Execution state and has defined behavior in the other Execution state, this is an example of a bit or field with behavior that depends on the architectural context.

This means the definition of RES0 for register fields is:

If a bit is RES0 in all contexts

It is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 0. In this case:
   - Reads of the bit always return 0.
   - Writes to the bit are ignored.
2. The bit can be written. In this case:
   - An indirect write to the register sets the bit to 0.
   - A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.

     If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- A direct write to the bit must update a storage location associated with the bit.
- The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this Manual explicitly defines additional properties for the bit.

Whether RES0 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a field-by-field basis.

If a bit is RES0 only in some contexts

When the bit is described as RES0:

- An indirect write to the register sets the bit to 0.
- A read of the bit must return the value last successfully written to the bit, by either a direct or an indirect write, regardless of the use of the register when the bit was written.

  If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
- A direct write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as RES0, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

- Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
- The value of the bit can be written, and a read returns the last value written to the bit.

A bit that is RES0 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

- Must not rely on the bit reading as 0.
- Must use an SBZP policy to write to the bit.

The RES0 description can apply to bits or bitfields that are read-only, or are write-only:

- For a read-only bit, RES0 indicates that the bit reads as 0, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES0 indicates that software must treat the bit as SBZ.

This RES0 description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

In body text, the term RES0 is shown in SMALL CAPITALS.

See also Read-As-Zero (RAZ), RES1, Should-Be-Zero-or-Preserved (SBZP), UNKNOWN.

RES1

A reserved bit or field with *Should-Be-One-or-Preserved (SBOP)* behavior. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory, for example in translation table descriptors.

Within the architecture, there are some cases where a register bit or bitfield:

- Is RES1 in some defined architectural context.
- Has different defined behavior in a different architectural context.

Note

- RES1 is not used in descriptions of instruction encodings.
- Where an AArch32 System register is *Architecturally mapped* to an AArch64 System register, and a bit or field in that register is RES1 in one Execution state and has defined behavior in the other Execution state, this is an example of a bit or field with behavior that depends on the architectural context.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

This means the definition of RES1 for register fields is:

If a bit is RES1 in all contexts

It is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 1. In this case:
   - Reads of the bit always return 1.
   - Writes to the bit are ignored.
2. The bit can be written. In this case:
   - An indirect write to the register sets the bit to 1.
   - A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.

     If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
   - A direct write to the bit must update a storage location associated with the bit.
   - The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this Manual explicitly defines additional properties for the bit.

Whether RES1 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a field-by-field basis.

If a bit is RES1 only in some contexts

When the bit is described as RES1:

- An indirect write to the register sets the bit to 1.
- A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.

  Note

  As indicated in this list, this value might be written by an indirect write to the register.

  If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
- A direct write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as RES1, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

- Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
- The value of the bit can be written, and a read returns the last value written to the bit.

A bit that is RES1 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

- Must not rely on the bit reading as 1.
- Must use an SBOP policy to write to the bit.

The RES1 description can apply to bits or bitfields that are read-only, or are write-only:

- For a read-only bit, RES1 indicates that the bit reads as 1, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES1 indicates that software must treat the bit as SBO.

This RES1 description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

In body text, the term RES1 is shown in SMALL CAPITALS.

See also Read-As-One (RAO), RES0, Should-Be-One-or-Preserved (SBOP), UNKNOWN.

Reserved

Unless otherwise stated:

- Instructions that are reserved or that access reserved registers have UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior.
- Bit positions described as reserved are:
  - In an RW or WO register, RES0.
  - In an RO register, UNK.

See also CONSTRAINED UNPREDICTABLE, RES0, RES1, UNDEFINED, UNK, UNPREDICTABLE.

RISC

Reduced Instruction Set Computer.

Rounding error

The value of the rounded result of an arithmetic operation minus the exact result of the operation.

Rounding mode

Specifies how the exact result of a floating-point operation is rounded to a value that is representable in the destination format. The rounding modes are defined by the *IEEE Standard for Floating-point Arithmetic*, see *Floating-point standards, and terminology* on page A1-48.

Saturated arithmetic

Integer arithmetic in which a result that would be greater than the largest representable number is set to the largest representable number, and a result that would be less than the smallest representable number is set to the smallest representable number. Signed saturated arithmetic is often used in DSP algorithms. It contrasts with the normal signed integer arithmetic used in ARM processors, in which overflowing results wrap around from $+2^{31}–1$ to $–2^{31}$ or vice versa.

SBO

See Should-Be-One (SBO).

SBOP

See Should-Be-One-or-Preserved (SBOP).

SBZ

See Should-Be-Zero (SBZ).

SBZP

See Should-Be-Zero-or-Preserved (SBZP).

Security hole

A mechanism by which execution at the current level of privilege can achieve an outcome that cannot be achieved at the current or a lower level of privilege using instructions that are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. The ARM architecture forbids security holes.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

Self-modifying code

Code that writes one or more instructions to memory and then executes them. When using self-modifying code, you must use cache maintenance and barrier instructions to ensure synchronization. For more information, see *Caches and memory hierarchy* on page B2-70.

Set

See Cache sets.

Should-Be-One (SBO)

Hardware must ignore writes to the field.

ARM strongly recommends that software writes the field as all 1s. If software writes a value that is not all 1s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as 1, or to a field that should be written as all 1s.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

Should-Be-One-or-Preserved (SBOP)

From the introduction of the ARMv8 architecture, the description *Should-Be-One-or-Preserved (SBOP)* is superseded by *RES1*.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Note

The ARMv7 Large Physical Address Extension modified the definition of SBOP for register bits that are SBOP in some but not all contexts. The behavior of these bits is covered by the *RES1* definition, but not by the generic definition of SBOP given here.

Hardware must ignore writes to the field.

If software has read the field since the PE implementing the field was last reset and initialized, it must preserve the value of the field by writing the value that it previously read from the field. Otherwise, it must write the field as all 1s.

If software writes a value to the field that is not a value previously read for the field and is not all 1s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

Should-Be-Zero (SBZ)

Hardware must ignore writes to the field.

ARM strongly recommends that software writes the field as all 0s. If software writes a value that is not all 0s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as 0, or to a field that should be written as all 0s.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

Should-Be-Zero-or-Preserved (SBZP)

From the introduction of the ARMv8 architecture, the description *Should-Be-Zero-or-Preserved (SBZP)* is superseded by *RES0*.

Note

The ARMv7 Large Physical Address Extension modified the definition of SBZP for register bits that are SBZP in some but not all contexts. The behavior of these bits is covered by the *RES0* definition, but not by the generic definition of SBZP given here.

Hardware must ignore writes to the field.

If software has read the field since the PE implementing the field was last reset and initialized, it must preserve the value of the field by writing the value that it previously read from the field. Otherwise, it must write the field as all 0s.

If software writes a value to the field that is not a value previously read for the field and is not all 0s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

Signaling NaNs Cause an Invalid Operation exception whenever any floating-point operation receives a signaling NaN as an operand. Signaling NaNs can be used in debugging, to track down some uses of uninitialized variables.

Signed immediate and offset fields

Are encoded in two's complement notation unless otherwise stated.

SIMD Single-Instruction, Multiple-Data.

The SIMD instructions in AArch32 state are:

- The instructions summarized in *Parallel addition and subtraction instructions* on page F1-2294.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

- The Advanced SIMD instructions summarized in *Advanced SIMD and floating-point instructions* on page E1-2217, when operating on vectors.

  Note

  In ARMv7, some VFP instructions can operate on vectors. However, ARM deprecates those instruction uses, and strongly recommends that Advanced SIMD instructions are always used for vector operations.

Simple sequential execution
The behavior of an implementation that fetches, decodes and completely executes each instruction before proceeding to the next instruction. Such an implementation performs no speculative accesses to memory, including to instruction memory. The implementation does not pipeline any phase of execution. In practice, this is the theoretical execution model that the architecture is based on, and ARM does not expect this model to correspond to a realistic implementation of the architecture.

Single-copy atomicity
The form of atomicity described in *Properties of single-copy atomic accesses* on page B2-81.

See also Atomicity, Multi-copy atomicity.

Single-precision value
A 32-bit word that is interpreted as a basic single-precision floating-point number according to the *IEEE Standard for Floating-point Arithmetic*.

Spatial locality The observed effect that after a program has accessed a memory location, it is likely to also access nearby memory locations in the near future. Caches with multi-word cache lines exploit this effect to improve performance.

Special-purpose register
One of a specified set of registers for which all direct and indirect reads and writes to the register appear to occur in program order relative to other instructions, without the need for any explicit synchronization:

- *Special-purpose registers* on page C5-287 specifies the AArch64 Special-purpose registers.
- *AArch32 Special-purpose registers* on page G1-3660 lists the AArch32 Special-purpose registers.

T32 instruction One or two halfwords that specify an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in T32 state. T32 instructions must be halfword-aligned.

T32 instructions were previously called Thumb instructions.

See also A32 instruction, A64 instruction, T32 state.

T32 state The AArch32 Instruction set state in which the PE executes T32 instructions.

T32 state was previously called Thumb state.

See also A32 state, T32 instruction.

Taken locally An exception that is taken locally means an exception that is taken to the default Exception level, and is not routed to another Exception level.

Temporal locality
The observed effect that after a program has accesses a memory location, it is likely to access the same memory location again in the near future. Caches exploit this effect to improve performance.

Thumb instruction
See T32 instruction.

TLB *See* Translation Lookaside Buffer (TLB).

TLB lockdown A way to prevent specific translation table walk results being accessed. This ensures that accesses to the associated memory areas never cause a translation table walk.

Translation Lookaside Buffer (TLB)
A memory structure containing the results of translation table walks. They help to reduce the average cost of a memory access. Usually, there is a TLB for each memory interface of the ARM implementation.

Copyright © 2013-2016 ARM Limited or its affiliates. All rights reserved.
Non-Confidential - Beta

Translation table
A table held in memory that defines the properties of memory areas of various sizes from 1KB to 1MB.

Translation table walk
The process of doing a full translation table lookup. It is performed automatically by hardware.

Trap enable bits In VFPv2, VFPv3U, and VFPv4U, determine whether trapped or untrapped exception handling is selected. If trapped exception handling is selected, the way it is carried out is IMPLEMENTATION DEFINED.

Unaligned An unaligned access is an access where the address of the access is not aligned to the size of an element of the access.

Unaligned memory accesses
Are memory accesses that are not, or might not be, appropriately halfword-aligned, word-aligned, or doubleword-aligned.

Unallocated Except where otherwise stated in this manual, an instruction encoding is unallocated if the architecture does not assign a specific function to the entire bit pattern of the instruction, but instead describes it as CONSTRAINED UNPREDICTABLE, UNDEFINED, UNPREDICTABLE, or as an unallocated hint instruction.

A bit in a register is unallocated if the architecture does not assign a function to that bit.

See also CONSTRAINED UNPREDICTABLE, UNDEFINED, UNPREDICTABLE.

UNDEFINED Indicates an instruction that generates an Undefined Instruction exception.

In body text, the term UNDEFINED is shown in SMALL CAPITALS.

See also *Undefined Instruction exception* on page G1-3707.

Unified cache Is a cache used for both processing instruction fetches and processing data loads and stores.

Unindexed addressing
Means addressing in which the base register value is used directly as the virtual address to send to memory, without adding or subtracting an offset. In most types of load/store instruction, unindexed addressing is performed by using offset addressing with an immediate offset of 0. The `LDC`, `LDC2`, `STC`, and `STC2` instructions have an explicit unindexed addressing mode that permits the offset field in the instruction to specify additional coprocessor options.

UNK An abbreviation indicating that software must treat a field as containing an UNKNOWN value.

Hardware must implement the bit as read as 0, or all 0s for a multi-bit field. Software must not rely on the field reading as zero.

See also UNKNOWN.

UNK/SBOP Hardware must implement the field as Read-As-One, and must ignore writes to the field.

Software must not rely on the field reading as all 1s, and except for writing back to the register it must treat the value as if it is UNKNOWN. Software must use an SBOP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also Read-As-One (RAO), Should-Be-One-or-Preserved (SBOP), UNKNOWN.

UNK/SBZP Hardware must implement the bit as Read-As-Zero, and must ignore writes to the field.

Software must not rely on the field reading as all 0s, and except for writing back to the register must treat the value as if it is UNKNOWN. Software must use an SBZP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also Read-As-Zero (RAZ), Should-Be-Zero-or-Preserved (SBZP), UNKNOWN.

UNKNOWN An UNKNOWN value does not contain valid data, and can vary from moment to moment, instruction to instruction, and implementation to implementation. An UNKNOWN value must not return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE, are not CONSTRAINED UNPREDICTABLE, and do not return UNKNOWN values.

An UNKNOWN value must not be documented or promoted as having a defined value or effect.

In body text, the term UNKNOWN is shown in SMALL CAPITALS.

See also CONSTRAINED UNPREDICTABLE, UNDEFINED, UNK, UNPREDICTABLE.

UNPREDICTABLE

Means the behavior cannot be relied upon. UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE.

UNPREDICTABLE behavior must not be documented or promoted as having a defined effect.

An instruction that is UNPREDICTABLE can be implemented as UNDEFINED.

Execution at Non-secure EL1 or EL0 of an instruction that is UNPREDICTABLE can be implemented as generating a trap exception that is taken to EL2, provided that at least one instruction that is not UNPREDICTABLE and is not CONSTRAINED UNPREDICTABLE causes a trap exception that is taken to EL2.

In body text, the term UNPREDICTABLE is shown in SMALL CAPITALS.

See also CONSTRAINED UNPREDICTABLE.

VA *See* Virtual address (VA).

VFP In ARMv7, an extension to the ARM architecture, that provides single-precision and double-precision floating-point arithmetic.

Virtual address (VA)

An address generated by an ARM PE. This means it is an address that might be held in the program counter of the PE. For a PMSA implementation, the virtual address is identical to the physical address.

See also Intermediate physical address (IPA), Physical address (PA).

Watchpoint A debug event triggered by an access to memory, specified in terms of the address of the location in memory being accessed.

Way *See* Cache way.

WI Writes Ignored. In a register that software can write to, a WI attribute applied to a bit or field indicates that the bit or field ignores the value written by software and retains the value it had before that write.

See also RAO/WI, RAZ/WI, RES0, RES1.

Word A 32-bit data item. Words are normally word-aligned in ARM systems.

Word-aligned Means that the address is divisible by 4.

Write-allocate cache

A cache in which a cache miss on storing data causes a cache line to be allocated into the cache.

Write-back cache

A cache in which when a cache hit occurs on a store access, the data is only written to the cache. Data in the cache can therefore be more up-to-date than data in main memory. Any such data is written back to main memory when the cache line is cleaned or reallocated. Another common term for a write-back cache is a *copy-back cache*.

Write-through cache

A cache in which when a cache hit occurs on a store access, the data is written both to the cache and to main memory. This is normally done via a write buffer, to avoid slowing down the PE.

Write buffer A block of high-speed memory that optimizes stores to main memory.
